SOME experiments carried out by R. S. Creed and Ragnar Granit in the Department of Physiology at Oxford² throw some light on the obscure subject of the respective functions of the rods and cones of the retina. According to the "duplexity" theory elaborated by J. v. Kries in 1891 and now widely but not universally accepted, the cones serve for vision in bright light while the rods are part of a different mechanism adapted for vision in twilight. These new experiments have to do with the latency of negative after-images following stimulation of different areas of the retina. As such experiments depend on the interpretation of subjective sensations they can only be carried out by trained observers under rigid precautions. Using small white discs of constant size on a dark ground at varying distance from the fixation-point, these observers found that the latent period before the appearance of the after-image is longest in the centre of the field of vision, shortening rapidly to a point about 2° from the fixation-point, then

"Ne quid nimis."

THE UNITY OF THINGS.

"Principalia non praeter necessitatem multiplicanda sunt." This axiom has held good in the limited sphere of clinical medicine for many generations, and no physician will willingly make two diagnoses where one will serve to cover the observed facts. When it comes to extending the same principle to a number of sciences, or to the whole universe, physician and scientist alike offer a far more cautious allegiance. This generation is experiencing a remarkable swing of the pendulum from the extreme concentration of the last on the bacteriological aspect of disease, which seemed in the first flush of its discovery to offer so easy and satisfactory an explanation. Now epidemiologists have realised that the presence of a "causative" organism does not constitute a diseased individual, much less an epidemic. They find themselves exploring again the ideas of Sydenham, which 30 years ago seemed so quaint. The "epidemic constitution" includes far more than the bacterium and all the complicated reactions of the host; it takes account of winds and waters, of temperature and humidity. Last week we had Mr. Kipling urging a distinguished medical audience—not quite ready yet to take him seriously—to include in their survey of the constitution a scan of the heavenly bodies. Now, in harmony with his concept, comes Sir William Bragg, reminding the audience at the Lloyd-Roberts lecture on Nov. 29th that the essence of Faraday's greatness and the basis of all his discoveries was his absorbing belief in the unity of Nature. From that belief and his singleness of aim to prove the underlying connexion between gravity, electrical magnetism, chemical action, cohesion, light, and heat—to the scientist of his day all isolated forces—we owe the whole electro-magnetic theory of light and "wireless," electroplating, electrotyping, electrolysis, and innumerable other "everyday" processes of this age. Because of the tremendous consequence of Faraday's work upon our modern activities and outlook, his diary has a peculiar interest for men of science and laymen alike. As presented by Sir William Bragg, the day to day record of Faraday's laboratory experiments and results, a million words in all, became a living human document, enshrining the lovable enthusiastic personality by whom it was penned. Faraday would write down, in the neat spidery handwriting of his period, all that he thought he might do, all that he did; his many failures and his rare and thrilling successes. Peculiarly dear to the heart of Sir William Bragg was the little word "but," written in capitals and heavily underlined, which breaks a fortnight's sequence of hundreds of unsuccessful experiments. Using very often the actual materials which Faraday had handled, rescued from cupboards in the Royal Institution, the lecturer repeated before the eyes of his audience the very experiments which had led the great scientist to his epoch-making discoveries. Holding a bar of magnetised iron in his hand, he approached a coil of wire connected to a galvanometer, and everybody in the hall saw its needle quiver. "It looks simple, doesn't it?" said Sir William. "But it moved the world." It was the beginning of the dynamo. The famous "but" referred to the experiment establishing the connexion between magnetism and light, and never was truer prophecy written than Faraday's note in his diary that day. "This fact will most likely prove exceeding fertile and of great value in the investigation of conditions of natural force." This

crucial experiment, too, the audience at the Royal Society of Medicine were able to see for themselves. In seeking for a connexion between gravity, on the one hand, and light and heat on the other, Faraday was less successful, and he never knew how hopeless was his quest with the material at his disposition. Many intermediate steps were needed before Einstein could predict the deflection by the sun of the ray of light from a planet. This is the centenary year of the beginning of Faraday's diary, and the entries continue until 1862. Faraday, as Sir William Hale-White pointed out in proposing a vote of thanks to Sir William Bragg, was a great lecturer and a great scientist, yet the world owes less to him for his experiments than for the spirit in which he performed them. The simplicity and single-mindedness expressed in his diary was a part of his whole life. The world of science has still something to learn from his message of unity in Nature.

MILK-BORNE DISEASES.

WITH the general improvement of the cleanliness of dairymen, the large-scale adoption of pasteurisation, and the greater efficiency of the departments responsible for controlling communicable diseases, large and explosive epidemics due to contamination of milk-supplies are now much less common than they were 20 years ago. Nevertheless, milk remains an important channel of infection and, indeed, a more interesting one as the elucidation of its association with epidemics becomes more difficult. Recent work in Denmark¹ and the United States of America² on undulant fever and cattle abortion suggests a new line of investigation into grouped cases of obscure febrile disease whose milk-supply may be from a common source. In our issue of Dec. 3rd, 1927, we had occasion to draw attention to the importance of watching the milk-supply in epidemics of poliomyelitis, and the evidence that milk may be implicated is fairly convincing. In recent years the occurrence of milk-borne paratyphoid has received a good deal of prominence, especially since Dr. W. V. Shaw's report³ to the Minister of Health on the Chorley outbreak of October, 1924, was published. New ideas, however, are not confined to diseases whose association with milk had not hitherto been suspected. The view that milk epidemics were invariably sudden and dramatic in their onset has had to be revised. It has been found that quite elaborate detective work may be needed to extricate milk-borne scarlet fever or diphtheria from the mass of cases ordinarily transmitted in any area, the clue being found in an unusual age-distribution of cases with a common source of milk. In diphtheria, especially, explosiveness is by no means characteristic, and this can be readily understood when the comparatively low degree of infectivity of the diphtheria bacillus in normal times and its destruction in acid media are kept in mind. The outbreak reported on p. 1201 of our present issue is one which might easily have been missed if it had been embedded in a large volume of cases directly infected by air-borne droplets, under which circumstances the age-distribution would have been almost the only incriminating evidence, since the number of cases was so small. The main interest of this epidemic, however, lies in the clinical and bacteriological confirmation of previous evidence that the diphtheria bacillus can live on the raw surface of the ulcers of cow-pox and that it may in this way continuously invade the milk over a period. The epidemic and the epizootic began and ended about the same time, and unquestionable diphtheria bacilli were isolated from the ulcerated cow's teats. As so often occurs in such investigations, the circumstantial evidence was confused by the presence of a diphtheria carrier who had no direct connexion

with the dairy work and by the occurrence on the farm lands subsequently of two cases of diphtheria in patients who, like so many farm labourers' children, were not consumers of fresh milk. At any rate, the facts of this carefully investigated little outbreak are of great interest as a reminder of a mode of milk contamination which had come to be rather discounted.

THE LETTERS OF JOHN RAY.

THE eighty-fourth year of the Ray Society saw the tercentenary of the birth of its eponym. The 114th volume of the proceedings¹ consists of unpublished letters of Ray, and amplifies the two volumes of life and correspondence issued by the society in 1846 and 1848 under the supervision of the then secretary, Dr. Edwin Lankester. Much information has come to light in the past 80 years, and the society is fortunate in having Mr. Gunther's scholarly work as a memorial of Ray's tercentenary. The present series of letters is the outcome of a rediscovery in the Bodleian Library of a number of Ray's letters, addressed for the most part to Aubrey and Lhwyd. The latter was keeper of the Ashmolean Museum, where, before their transference to the Bodleian, these letters were housed; their presence there appears to have been overlooked by Dr. Lankester. Fourteen letters are addressed to Aubrey and 15 to Lhwyd, the dates being 1690 to 1691. In 1890 the Bodleian acquired a further series of 26 letters from Ray to Lhwyd, of dates between 1689 and 1703. Nine letters dated 1679-1693 in Ray's holograph were found in the letter books of the Royal Society. Of the letters issued by Derham in 1718, mainly addressed to Martin Lister, many were not printed in full; the details of personal interest which were omitted have now been supplied. A chronological table of Ray's letters, published in 1848 and in the present volume, shows well how the gaps in the former volume are bridged by the present one. Of the first 19 letters, all addressed to Peter Courthope of Danny, only four are to be found in the 1848 volume. Two short lives of Ray, by Dale and Petiver, are here abridged, and the uncertainty of the exact date of Ray's birth is satisfactorily settled by a facsimile of the record in the parish register of 1627. Some of the letters in the present series are in Latin, but by far the greater number are in English and are extraordinarily interesting; they enable us to form some estimate of the great naturalist, the rectitude of whose character is proved by his refusal to sign the Solemn League and Covenant, which refusal deprived him of his Fellowship at Trinity College, Cambridge. His thirst for information is brought out strongly, as well as his willingness to impart his special knowledge to others.

Ray gives explicit instructions to his correspondents as to how books, plants, &c., are to be sent to him; over and over again he informs them that the Braintree carrier "innes at the Pewter-Pot, in Leadenhall-street, and comes out of town on Friday mornings weekly." His letters contain many shrewd comments on his contemporaries; of Father Kircher he says: "I account him a credulous person, possessed with ye vanity of most of ye religious of his church who delight to tell strange and miraculous tales to amuse and delude ye vulgar." He gives as a reason for not sending Lhwyd a copy of one of his books, "the bookseller concerned in that copy is so stingy and covetous as not to allow me copies to present my friends." In the matter of Dr. Burnet's "Theory of ye earth": "A great deal of stuffe he hath about the mysticall and allegorical physiology of the ancients, which I understand not, nor I believe have I neither." A little further on he says of the same matter, "methinks his book in many places sounds rank of the other sort." Some few details of Ray's work of interest appear in places. Thus for his

diarrhoea he found "a very easy and pleasant medicine to be Naples-bisket boiled in milk." The lost letters of Ray to Lister and Tancred Robinson, 1683-1704, are here epitomised from Dering and a very complete index, with references to the 1848 and 1928 volumes, completes a work which illustrates well the scientific attitude and breadth of mind of one of the greatest English naturalists of all time.

INJECTION TREATMENT OF VARICOSE VEINS.

ON the whole the operative treatment of varicose veins cannot be said to have given good results. Seldom can a really successful issue be predicted; usually surgery does no more than reduce disability, and in the remaining cases there is little or no improvement. The popularity of the various forms of injection treatment is rapidly relegating operative measures to a position of merely historic importance. Of its immediate success there is no doubt, though time alone will show what permanence may be expected. Like other forms of treatment, it is, of course, not entirely devoid of risks, and something may be learned of these from a paper¹ in which McPheeters and Rice review from the literature and from their own experience the complications which may follow. The accidents formerly associated with the method were due to the employment of coagulant solutions or to lack of aseptic precautions, but now a total of 53,000 cases treated by injection has been recorded in the literature, with but seven deaths. Of these fatalities pulmonary emboli were responsible for four, whilst the remaining patients died from septic thrombophlebitis, mercury poisoning, and septicæmia respectively. Three other fatal cases have also been reported, but in these the issue is obscured by the presence of some other disease which might equally have been responsible for death. When septic thrombophlebitis occurs these writers consider it much more likely to be due to the lighting up of a latent phlebitis than to the introduction of organisms at the time of injection. On their showing the published figures indicate an extremely low mortality from injection treatment—a mortality many times less than that associated with operation. Of the less serious local complications sloughing and sepsis should be avoidable with proper technique, and the danger of thrombosis developing in the deep veins of the limb has been proved more theoretical than real. The new treatment is admittedly in its infancy, but the results have been very encouraging. The technique is comparatively simple, serious complications almost non-existent, and with due care a cure can be effected in nearly every case.

THE RODS AND CONES.

SOME experiments carried out by R. S. Creed and Ragnar Granit in the Department of Physiology at Oxford² throw some light on the obscure subject of the respective functions of the rods and cones of the retina. According to the "duplicity" theory elaborated by J. v. Kries in 1894 and now widely but not universally accepted, the cones serve for vision in bright light while the rods are part of a different mechanism adapted for vision in twilight. These new experiments have to do with the latency of negative after-images following stimulation of different areas of the retina. As such experiments depend on the interpretation of subjective sensations they can only be carried out by trained observers under rigid precautions. Using small white discs of constant size on a dark ground at varying distance from the fixation-point, these observers found that the latent period before the appearance of the after-image is longest in the centre of the field of vision, shortening rapidly to a point about 2° from the fixation-point, then

with the dairy work and by the occurrence on the farm lands subsequently of two cases of diphtheria in patients who, like so many farm labourers' children, were not consumers of fresh milk. At any rate, the facts of this carefully investigated little outbreak are of great interest as a reminder of a mode of milk contamination which had come to be rather discounted.

THE LETTERS OF JOHN RAY.

THE eighty-fourth year of the Ray Society saw the tercentenary of the birth of its eponym. The 114th volume of the proceedings¹ consists of unpublished letters of Ray, and amplifies the two volumes of life and correspondence issued by the society in 1846 and 1818 under the supervision of the then secretary, Dr. Edwin Lankester. Much information has come to light in the past 80 years, and the society is fortunate in having Mr. Gunther's scholarly work as a memorial of Ray's tercentenary. The present series of letters is the outcome of a rediscovery in the Bodleian Library of a number of Ray's letters, addressed for the most part to Aubrey and Llwyd. The latter was keeper of the Ashmolean Museum, where, before their transference to the Bodleian, these letters were housed; their presence there appears to have been overlooked by Dr. Lankester. Fourteen letters are addressed to Aubrey and 15 to Llwyd, the dates being 1690 to 1691. In 1890 the Bodleian acquired a further series of 26 letters from Ray to Llwyd, of dates between 1680 and 1703. Nine letters dated 1670-1693 in Ray's holograph were found in the letter books of the Royal Society. Of the letters issued by Dorham in 1718, mainly addressed to Martin Lister, many were not printed in full; the details of personal interest which were omitted have now been supplied. A chronological table of Ray's letters, published in 1848 and in the present volume, shows well how the gaps in the former volume are bridged by the present one. Of the first 19 letters, all addressed to Peter Courthope of Danny, only four are to be found in the 1848 volume. Two short lives of Ray, by Dale and Petiver, are here abridged, and the uncertainty of the exact date of Ray's birth is satisfactorily settled by a facsimile of the record in the parish register of 1627. Some of the letters in the present series are in Latin, but by far the greater number are in English and are extraordinarily interesting; they enable us to form some estimate of the great naturalist, the rectitude of whose character is proved by his refusal to sign the Solemn League and Covenant, which refusal deprived him of his Fellowship at Trinity College, Cambridge. His thirst for information is brought out strongly, as well as his willingness to impart his special knowledge to others.

Ray gives explicit instructions to his correspondents as to how books, plants, &c., are to be sent to him; over and over again he informs them that the Braintree carrier "comes at the Pewter-Pot, in Leadenhall-street, and comes out of town on Friday mornings weekly." His letters contain many shrewd comments on his contemporaries; of Father Kircher he says: "I account him a credulous person, possessed with ye vanity of most of ye religious of his church who delight to tell strange and miraculous tales to amuse and delude ye vulgar." He gives as a reason for not sending Llwyd a copy of one of his books, "the bookeller concerned in that copy is so stingy and would not allow me copies to present my friends." In the matter of Dr. Burnt's "Theory of ye earth": "A great deal of stuffe he hath about the mystical and allegorical physiology of the elements, which I understand not, nor I believe myself neither." A little further on he says of the same matter, "methinks his book in many places is a work of the enthusiast." Some few details of Ray's interest appear in places. Thus for his

diarrhoea he found "a very easy and pleasant medicine to be Naples-bisket boiled in milk." The lost letters of Ray to Lister and Tancered Robinson, 1683-1704, are here epitomised from Dering and a very complete index, with references to the 1848 and 1928 volumes, completes a work which illustrates well the scientific attitude and breadth of mind of one of the greatest English naturalists of all time.

INJECTION TREATMENT OF VARICOSE VEINS.

ON the whole the operative treatment of varicose veins cannot be said to have given good results. Seldom can a really successful issue be predicted; usually surgery does no more than reduce disability, and in the remaining cases there is little or no improvement. The popularity of the various forms of injection treatment is rapidly relegating operative measures to a position of merely historic importance. Of its immediate success there is no doubt, though time alone will show what permanence may be expected. Like other forms of treatment, it is, of course, not entirely devoid of risks, and something may be learned of these from a paper¹ in which McPheeters and Rice review from the literature and from their own experience the complications which may follow. The accidents formerly associated with the method were due to the employment of coagulant solutions or to lack of aseptic precautions, but now a total of 53,000 cases treated by injection has been recorded in the literature, with but seven deaths. Of these fatalities pulmonary emboli were responsible for four, whilst the remaining patients died from septic thrombophlebitis, mercury poisoning, and septicæmia respectively. Three other fatal cases have also been reported, but in these the issue is obscured by the presence of some other disease which might equally have been responsible for death. When septic thrombophlebitis occurs these writers consider it much more likely to be due to the lighting up of a latent phlebitis than to the introduction of organisms at the time of injection. On their showing the published figures indicate an extremely low mortality from injection treatment—a mortality many times less than that associated with operation. Of the less serious local complications sloughing and sepsis should be avoidable with proper technique, and the danger of thrombosis developing in the deep veins of the limb has been proved more theoretical than real. The new treatment is admittedly in its infancy, but the results have been very encouraging. The technique is comparatively simple, serious complications almost non-existent, and with due care a cure can be effected in nearly every case.

THE RODS AND CONES.

SOME experiments carried out by R. S. Creed and Ragnar Granit in the Department of Physiology at Oxford² throw some light on the obscure subject of the respective functions of the rods and cones of the retina. According to the "duplicity" theory elaborated by J. v. Kries in 1894 and now widely but not universally accepted, the cones serve for vision in bright light while the rods are part of a different mechanism adapted for vision in twilight. These new experiments have to do with the latency of negative after-images following stimulation of different areas of the retina. As such experiments depend on the interpretation of subjective sensations they can only be carried out by trained observers under rigid precautions. Using small white discs of constant size on a dark ground at varying distance from the fixation-point, these observers found that the latent period before the appearance of the after-image is longest in the centre of the field of vision, shortening rapidly to a point about 2° from the fixation-point, then

The Clinical Interpretation of Aids to Diagnosis.

A Series of Special Articles contributed by Invitation.

XIV.

THE DETERMINATION OF THE PRESENCE AND SIGNIFICANCE OF REDUCING SUBSTANCES IN URINE.

BY E. C. DODDS, M.D., Ph.D., M.R.C.P. LOND.,
PROFESSOR OF BIOCHEMISTRY, UNIVERSITY OF LONDON.

I.*—THE PRACTITIONER'S RESULTS.

THE question as to whether urine contains sugar or not is one which seems to present very great difficulties to practitioners. Nearly every student up for final examinations can answer correctly the question: "How would you determine the nature of the reducing substance in the urine?" But his knowledge must be mainly theoretical, because, when he meets such a problem in practice, he usually sends the urine to the laboratory asking the biochemist to find out whether the offending substance is glucose or not.

In attacking this problem there are two main avenues of approach. Firstly, the academic or examination method, which consists of giving a list of the possible reducing substances in urine. Starting with glucose, the list wanders on through excess of uric acid and creatinin to glycuronic acid, lactose, and finishes up triumphantly with homogentisic acid. The methods for differentiating between this imposing list are usually very complicated, and one of the most popular among students up for examinations is to prepare an osazone of the sugar and to take its melting-point. Any more unpractical and unsuitable method for the ordinary person could not possibly be imagined. The melting-points of the osazones of the normal sugars are very close, and before the analyst could obtain anything like the theoretical figures many purifications and recrystallisations would have to be done.

The Use of Benedict's Solution.

The second way of approaching this problem is from the practical standpoint, and the most important factor in obtaining the correct answer is to use the right type of copper solution for testing the reducing power of the urine. This is not Fehling's solution. I say this not out of any disrespect for Fehling, or with any lack of appreciation of the pioneer work that he did half a century ago. It is merely meant to indicate that when new, better, and simpler methods are available, it is a mistake to adhere to the archaic. The solution used should be Benedict's solution, which can be bought or can be made up in the following way.

Dissolve 173 g. of crystallised sodium citrate and 100 g. anhydrous sodium carbonate in 700 c.cm. water, and 17.3 g. fine crystallised copper sulphate in 100 c.cm. water. Pour the copper sulphate solution into the other, and make up the volume to 1000 c.cm.

The method of performing the test is quite standardised, which is not the case with Fehling's test. 5 c.cm. of Benedict's reagent are placed in a test-tube and 8 drops of the suspected urine added; after shaking, the test-tube is either heated in the flame and the contents boiled for five minutes, or else it is placed in boiling water for five minutes. When it has been cooled, the original blue colour of the contents of the tube will be replaced by a brown colour if the reducing substance be a carbohydrate. Various degrees of reduction, such as opalescence and greenish colour, indicate varying quantities of reducing substance present.

* Part II. will appear next week.

Distinction between Glucose, Lactose, and Pentose.

Apart from homogentisic acid, which is so rarely present that it need not be considered, Benedict's solution is only reduced by carbohydrates such as glucose, lactose, and pentose. If there is still any doubt whether the substance is glucose, then a fermentation test can be performed. This is so simple that anyone can do it without elaborate laboratory facilities. All that is required is a little yeast which is made into a thin paste with the suspected urine and placed in a fermentation tube. A similar paste is also made with urine which is known to be free from glucose, and with urine to which glucose has been added, and the three tubes are left in a warm place overnight. The next morning, if the suspected urine contains sugar, gas will be present in the top of the tube and also in the tube containing the positive control, while there will be no gas above the negative control. It must be remembered that the controls are part of the test, since there are some yeasts which will produce gas when glucose is absent, and others which will not ferment sugar.

Provided the instructions are carefully adhered to, there are no fallacies in Benedict's test. The only error which, to my knowledge, has ever occurred in the employment of Benedict's test, arose under very peculiar circumstances. A physician informed me that Benedict's test was quite useless. He had followed out the instructions very carefully, taking 5 c.cm. of the solution and 8 drops of the urine, and on boiling nothing had happened. A urine which he knew to give a very strong reduction with Fehling's solution gave a mysterious white precipitation with Benedict's solution. To those accustomed to laboratory procedures the answer was obvious: he had purchased Benedict's quantitative solution which only gives a reduction when relatively large quantities of glucose are present, and is specially designed so that no reddish-brown colour appears. It is, therefore, important to see that one is working with the correct reagent—namely, Benedict's qualitative solution.

Benedict's reagent is specially constituted so that it will not be reduced by such normal constituents of the urine as uric acid, creatinin, or glycuronic acid. It follows, therefore, that if this solution be used as the test fluid, then practically all the difficulties usually encountered will vanish. A positive reaction with Benedict's qualitative solution indicates the presence of the carbohydrate, and this, in the urine, is only likely to be glucose, pentose, or lactose. A fermentation test will decide definitely whether or not it is glucose, so that in the majority of cases Benedict's test in combination with a fermentation test will be sufficient to indicate the nature of the reducing substance. Should, however, the Benedict test be positive and the fermentation test negative, then it will be necessary to proceed with further reactions.

If *pentose* be suspected, then the urine can be tested by means of Bial's test.

The reagent consists of 1.5 g. orcinol, 500 g. of fuming HCl, and 20-30 drops of 10 per cent. FeCl₃ solution; 5 c.cm. of this is boiled in a test-tube and 2 or 3 c.cm. of urine added. When the tube is removed from the flame the solution turns a green colour if pentose is the reducing substance.

If, however, this test is also negative, then lactose must be suspected, and the only certain method of detecting this is to prepare an osazone. This may be done as follows.

About 50 c.cm. of urine are measured out into a test-tube and 1 c.cm. of glacial acetic acid is added. Enough phenylhydrazine hydrochloride as is required to cover sixpence is added, and this is followed by slightly more sodium acetate (about as much as is required to cover ninepence—i.e., intermediate between sixpence and a shilling). The tube is placed in a boiling water-bath and after half hour's heating the contents are filtered and then allowed to cool, when the characteristic crystals separate out.

Quantitative Estimation of Glucose in General Practice.

With regard to the quantitative estimation of glucose in the urine, it is difficult to recommend any simple method. By far the easiest method is to use some form of polarimeter, of which the most simple is the daylight type, the scale being graduated directly in percentages of glucose. It is only necessary to pour the urine into the observation tube and to adjust the lever until both sides of the polarimetric field are of the same tint. The percentage of sugar can then be read off from the scale. The only disadvantage to this method is the initial expense, since the apparatus costs from £5 to £6. When, however, one considers the saving in time, washing up, and the purchase of solutions, it is doubtful whether the instrument is really a costly one. If the urine is very dark in colour, it may be necessary to perform a preliminary precipitation with basic lead acetate solution. This is done by adding one volume of basic lead acetate to four volumes of urine; the mixture is shaken and filtered, and the perfectly clear, colourless filtrate is then poured into the polarimetric observation tube. In this case, of course, it is necessary to add one-quarter of the reading on the scale to allow for the dilution of the original urine.

This method requires no special skill and takes very little time, so that it is eminently suited to the needs of general practice. If, however, it is felt that the initial expense of the polarimeter is too heavy, then one of the volumetric methods may be used. In this case it is recommended that Benedict's quantitative test be employed. The test is performed as follows.

Into a small flask 25 c.cm. of the quantitative solution are pipetted and 3 to 4 g. of anhydrous sodium carbonate are added, the whole being brought to the boil. Urine is added slowly from a burette until the reagent turns from clear blue to a bluish-white opalescence, when the urine is added still more slowly until the colour is completely gone. This preliminary titration gives some idea of the concentration of the sugar, and on the knowledge thus obtained a second titration is performed with the urine diluted so that about 10 c.cm. will reduce the reagent. Quite a simple calculation will give a fairly accurate result. The most important point in performing this test is to run the urine into the boiling reagent at the same rate each time so that the error is constant throughout a series of titrations.

The tests set out above should rob the problem of its terrors. Very difficult cases rarely arise, and after many years of experience in the large routine of a chemical laboratory I can only recall some half-dozen instances when more than ordinary knowledge and care was required to ascertain the nature of the reducing substance. When, however, the nature of the substance is clear, there remains the problem of estimating the clinical significance of the presence in the urine of any one of the sugars in small or in large quantities.

The most important fact to realise is that the odds are in favour of a reducing substance in the urine being glucose, and that really atypical forms of reduction are usually due to such mundane factors as dirty test-tubes or inaccurately made-up test solutions.

HOSPITAL SAVING ASSOCIATION.—There are now 200 groups, containing 200,000 contributors, and the income is at the rate of £100,000. During the 12 months ended 31st March 1928, the co-operating hospitals treated 1,000,000 patients, of whom 21,787 were in-patients. The total payment for services to hospitals and hospitals of patients was £155,645; management charges £22,111. A £125,000 fund has been raised for the purpose of the association.

LONDON FLUORIDE HOSPITAL PATIENTS.—Last week 100 patients of York had the fluorine treatment of an infection of the respiratory tract at the Hospital in London. The patients were treated by the method of Dr. J. H. M. Jones, and the results were very satisfactory. The patients were treated by the method of Dr. J. H. M. Jones, and the results were very satisfactory. The patients were treated by the method of Dr. J. H. M. Jones, and the results were very satisfactory.

*Special Articles.*MILK-BORNE DIPHTHERIA
ASSOCIATED WITH DIPHTHERITIC
INFECTION OF COWS' UDDERS.

BY C. J. MCSWEENEY, M.B.N.U.I., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, CARDIFF;
AND

W. PARRY MORGAN, M.D. CAMB., B.Sc. LOND.,
PATHOLOGIST AND BACTERIOLOGIST, CITY AND COUNTY PUBLIC
HEALTH LABORATORY, CARDIFF.

BETWEEN Sept. 21st and 27th, 1928, seven cases of diphtheria with a common milk-supply and of an unusual age-distribution occurred in a district of Cardiff where the disease had not hitherto been prevalent. The cases occurred in the following sequence:—

Sex.	Age.	Dates of notification.	Date of onset.
Female ..	5	Sept. 23rd	Sept. 23rd
Female ..	20	" 24th	" 21st
Male ..	13	" 24th	" 21st
Female ..	22	" 27th	" 23rd
Male ..	11	Oct. 2nd	" 20th
Female ..	6½	" 4th	" 27th
Female ..	3½	" 6th	" 18th-20th*

* Indefinite.

When the fourth case came to the knowledge of the health department it was considered that there was sufficient likelihood of milk infection to justify an investigation at the premises of the producer and of the retailer. As the producer's farm was situated outside the city boundaries the investigations here were carried out in co-operation with the medical officer of health of the district concerned. All persons at both establishments directly or indirectly connected with the milk, as well as the families of all employees who lived out, were examined on Sept. 27th, and throat swabs were taken in each case. The daughter of the farmer was found to be a carrier of diphtheria bacilli and was removed to an isolation hospital on Sept. 29th.

No further cases of diphtheria occurred on this particular milk-round after Sept. 27th, but two children of a cowman, aged 2 and 4 years, sickened with diphtheria on Oct. 11th and 13th respectively. These children had been swabbed together with all the members of the household on Sept. 27th and found to be negative. Since this date they had taken only tinned milk. The source of infection in these two late cases is therefore not clear, but raises interesting speculations.

As the cows in milk on the farm were found to be suffering from a vesicular eruption of the teats, swabs were taken from the lesions of six different animals on Oct. 3rd. The farmer stated that this condition, which had been diagnosed by a veterinarian as cow-pox, had existed in his milking herd for some three or four weeks previously and that practically all his cows had developed the disease. The city and county veterinary surgeons, Mr. P. J. Mullane and Mr. J. Howard Jones, who were present at the investigation of Oct. 3rd, examined the lesions and agreed with this diagnosis. Most of the cows which had not active lesions showed healed scars on the udders. The milkers on the farm said that some of them had "caught the pox" from the cows, but only if they had a cut or abrasion on the hands. At the time of visit the milkers showed no sores, but on the fingers of two of them, pulled clean, a small vesicular mark was seen. Thus, of course, a characteristic of cow-pox. The lesions on the udders of the cows were of the type which is

edges, the base being covered with a loose slough which, when removed, caused bleeding. The ulcers were approximately 1 inch across as a maximum and varied in length from 1-2 inches.

Bacteriological Investigation.

Swabs labelled 1-6 were taken from the sores on the udders of six cows. Cultures were made on serum. Those from swabs 2 and 5 showed typical diphtheria bacilli mixed with a profuse growth of Gram-positive cocci. With a view to isolating the bacilli, subcultures were made, but without success. Also, swabs were again taken on Oct. 5th from cows 2 and 5, but the second swabs showed no typical diphtheria bacilli. By this time the lesions had almost healed and the epidemic of cow-pox had practically come to an end. Cultures 2 and 5 were tested for virulence by making a suspension in saline and injecting 0.4 c.cm. into one guinea-pig and 0.6 c.cm. with 300 units of antitoxin into another. Culture 2 proved to be virulent, the unprotected animal being found dead at the end of 40 hours. No. 5, in which the diphtheria bacilli were not numerous, failed to kill. Cultures were made from the local lesion of the guinea-pig that died and a pure culture obtained. The virulence of this was tested in the same way as the primary mixed culture, the unprotected animal dying in under 40 hours. The post-mortem examinations showed local cedema, fluid in the serous cavities, and very congested suprarenal bodies.

Discussion.

The isolation of virulent diphtheria bacilli from similar lesions of cows' udders has been reported by Dean and Todd¹ and by Ashby.² In Dean and Todd's case experiments were made on calves with a view to finding how the ulcers were related to cow-pox on the one hand and to diphtheria on the other. They transmitted the lesions to vaccinated and unvaccinated calves, but were not able to demonstrate diphtheria bacilli in any inoculated animals. They were not able to infect calves with the virulent diphtheria bacilli isolated from the original case. These observations make it clear that ulcers on cows' udders may become infected with virulent diphtheria bacilli, but that this infection is accidental and not the cause of the ulcers.

In the present instance it is probable that the udder condition was the main source of infection of the milk, although absolute proof is lacking. Searching inquiries failed to associate the farmer's daughter (who was found to be a carrier) with the milking operations, and it seemed to be certain that she never had occasion to be in contact with any of the milkers. The precise way in which the cow-pox lesions became infected with diphtheria bacilli remains, therefore, unascertained. There had been no history of sore-throats amongst the milkers or farm hands and swabs from their throats gave negative results. It is possible, however, that one of them, although negative at the swabbing on Sept. 27th, was really a carrier of virulent diphtheria bacilli and responsible for the infection of the teat ulcers, and it is most likely that this person was either the father of the two children who sickened later or another cowman who lodged with them.

The interest of this outbreak lies in the demonstration of virulent diphtheria bacilli in a pathological lesion affecting the udders of cows, milk from which was known to have transmitted diphtheria. It is clear that in investigating outbreaks of milk-borne diphtheria local pathological conditions in the cows concerned should constantly be looked for, and, if discovered, should be fully explored by bacteriological methods.

We are indebted to Dr. Ralph M. F. Picken, medical officer of health, Cardiff, at whose suggestion the udders were swabbed, for his kind permission to publish these notes.

GENERAL MEDICAL COUNCIL.

WINTER SESSION, 1928.

PENAL CASES.

TUESDAY, NOV. 27TH.

IN accordance with custom, penal cases were heard in public and the Council deliberated on their findings in camera.

Reported by the Dental Board of the United Kingdom.

The Case of Joseph Jennings, registered as of 12, Market-street, Lurgan, "Dentist, 1921." This practitioner had appeared before the Board for persistent canvassing, in spite of a warning issued to him early in the year. The respondent did not appear in answer to his notice. The Council directed that his name be erased from the Register.

ADJOURNED FROM NOV. 24TH, 1927.

The Case of John Joseph Macabe, registered as of 58, Brunswick-street, Chorlton-on-Medlock, Manchester, M.B., B.Ch. 1918, N.U. Irel. This respondent had been convicted before magistrates of assault on one occasion and of drunkenness on four occasions, but the Council had postponed judgment for a year. Mr. Macabe was not present, and a letter from him was read by the Council's solicitor excusing himself on the ground of ill-health and enclosing testimonials to his sobriety and general good behaviour since his appearance before them. The Council, having considered this evidence, decided not to erase his name from the Register.

The Case of John McGhee, registered as of Station-road, Galston, Ayrshire, M.B., Ch.B. 1923, U. Glasg., who had been convicted before magistrates on two occasions of driving a motor-car to the public danger and once of being drunk in charge of a motor-car. The Council had postponed judgment for a year. The respondent appeared, and the Council's solicitor read testimonials furnished by him concerning his character and conduct during the period of probation. The Council did not see fit to erase his name from the Register.

ADJOURNED FROM MAY 28TH, 1928.

The Case of Robert Louis Portway, registered as of Flat 3, 80, Long Acre, W.C. 2. M.R.C.S. Eng. 1916, L.R.C.P. Lond. 1916, D.P.H.R.C.P.S. Eng. 1921, who had been convicted before magistrates once of drunkenness and once of drunkenness in charge of a motor-car. The Council had postponed judgment until their November session. Mr. Portway attended in answer to his notice, and the Council's solicitor read letters testifying to his good conduct in the interval; the Council did not see fit to direct the erasure of his name.

NEW CASES.

Drunkenness in Charge of a Motor Vehicle.

The Case of Bertie Edward Acland, registered as of 19, Sandown-road, Seaford, Liverpool, M.B., Ch.B. 1924, U. Liverpool, who was summoned to appear before the Council on the following charge: "That he was convicted at the Hanley Petty Sessions of the following misdemeanours, viz.:—

(1) On July 22nd, 1926, of being drunk in charge of a motor-car, and was fined £10 and witness fee £1 1s., or two months' imprisonment in default; and (2) on Oct. 2nd, 1928, of being drunk in charge of a motor-car, and was fined £20 and witnesses' fees £2 1s., and was disqualified for holding a driving licence for two years.

Dr. Acland was represented by Mr. B. de H. Pereira, counsel, instructed by Messrs. Le Brasseur and Oakley, on behalf of the London and Counties Medical Protection Society. The Council's solicitor laid the facts before the Council and read extracts from the proceedings before the magistrates. Respondent's adviser pointed out that respondent had already undergone severe punishment in the publicity which

these two cases had excited and in the loss of his driving licence for two years; he tendered on behalf of his client a solemn assurance to abstain altogether from alcohol in the future. The Council, considering this undertaking, postponed judgment for one year, subject to the usual condition that the respondent should before that time send to the Registrar names of some of his professional brethren who might be willing to testify to the correctness of his habits and conduct in the interval.

Alleged Abuse of Professional Relationship.

The Case of Arthur Fitzwilliam Comyn, registered as of White House, Ladies Walk, Hythe, M.R.C.S. Eng. 1907, L.R.C.P. Lond. 1907, M.B., B.Chir. 1910, U.Camb., who appeared on the following charge:—

That, being a registered medical practitioner, you abused your position by committing adultery with Violet Ella Gertrude Parsons, a married woman, with whom you stood in professional relationship, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated Dec. 9th, 1927, and made absolute on June 18th, 1928, in the case of Parsons v. Parsons and Comyn, in which you were the co-respondent. And in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect.

Dr. Comyn, who attended in answer to his notice, was represented by Mr. G. R. Blanco-White, instructed by Messrs. Reed and Reed.

The Council's solicitor, in laying the facts before the Council, remarked that adultery up till 1923 was admitted, and that since that time Mrs. Parsons had not been living in the same town as the respondent. The lady had been married in 1916, and the first child was born in 1918. Her husband, an officer in the mercantile marine, had been a good deal away from home, and they were a strangely ill-assorted pair. In 1920 the second child was born. In 1923 Mr. Parsons had come to England on leave, and, in consequence of a communication from his mother-in-law, had gone to Hythe to interview respondent. Staying the night in his own home, he had found letters from respondent to his wife, and had filed divorce proceedings, obtaining a decree nisi in 1927, made absolute in June, 1928. Although the adultery had been terminated for five years, the case had only just come to the notice of the Council. The Council's solicitor read a number of the letters, which were very numerous, pointing out that the couple had had constant quarrels. He produced the birth certificate of the second child, Patrick Miles Parsons, in March, 1922, and the death certificate, dated three weeks later and signed by Dr. Comyn. This, he submitted, constituted proof of professional relationship with Mrs. Parsons and her child. He called Mr. Shaw, the husband's solicitor, who gave formal evidence on the divorce proceedings. Cross-examined, witness stated that no complaint had ever been made that an alleged professional relationship had aggravated the offence of adultery. No evidence was offered that any professional services had been received. If the plaintiff had wished, he could have cited other co-respondents.

Dr. Comyn, giving evidence on his own behalf, stated that he had been in practice in Hythe since 1912. He was still living with his wife and his four children. He had met Mrs. Parsons first in August, 1914, when she was living with her parents. In 1920 he had met her again, and saw her a great deal until May, 1927. His relations with her had been social and not professional, and he had never been engaged as her doctor or her husband's doctor. He did not dispute adultery, but it was only after he had commenced this relationship that he had treated both her and her children with no idea of being paid for it. He had never met Mr. Parsons, except on one occasion, when the latter had called upon him at his home in 1927. He had never been employed by or for Mrs. Parsons's doctor. She had been consulted by him with her husband. Before her last visit to him, in fact, in 1920, she had been suffering with a severe cold and had been with

clerical work. A midwife had been present at the birth, and respondent had been present because Mrs. Parsons had wanted him and would not have anyone else. He had taken no part in the delivery. She had borrowed money in the same way as she had given clerical help—as a friend. In May, 1923, he had undergone an operation for appendicitis and had not seen her since.

Cross-examined, he admitted that Mrs. Parsons's father had asked him to keep an eye on her, but not in a medical sense. He had attended the boy Patrick at his death because Mrs. Parsons had asked him to. He had signed the death certificate. As far as he knew she had had no other medical attendant. He had used an expression in one of his letters: "I shall have to give up going professionally," meaning that they were not going to be friends any longer, and that therefore he would not see her in the professional capacity. There had never been any question of his sending in a bill, but if he had, no doubt her relatives would have paid it. Questioned by the President, he admitted that he had signed the death certificate in his professional capacity, although he had attended her as a friend. He had only drifted into attending her because he was her friend. In answer to the Legal Assessor, he admitted having given her advice about her children's whooping-cough, but said he had not seen much of them, as they were very healthy.

Colonel J. H. Hannay gave evidence that the respondent and Mrs. Parsons's family had been on social terms in 1921, and Mrs. Caroline Bullock testified that she had introduced Dr. Comyn to Mrs. Parsons's parents at Hythe in 1914, and that they were then "in and out of her house all day long." Although he was "the" doctor of Hythe, he had never attended her family; they were a very healthy family.

The Council found that the facts were not proved to their satisfaction.

WEDNESDAY, NOV. 28TH.

Association with a Self-Advertising Clinic.

The Case of George Bidie, registered as L.R.C.P., F.R.C.S. Edin., M.R.C.P. Lond., M.D.U. Edin., and of Mrs. Mary Joseph O'Flynn, registered as M.B., B.Ch., N.U. Irel. The charge upon which these practitioners had been summoned before the Council was as follows:—

That, being a registered medical practitioner, you have (1) associated with and/or been employed by an institution called "Alpine Sunray Treatments" which advertises for the purpose of obtaining patients; (2) that you have either directly or indirectly advertised and/or acquiesced in the publication of advertisements for the purpose of obtaining patients with a view to promoting your own professional advantage. And that in relation thereto you have been guilty of infamous or disgraceful conduct in a professional respect.

The complainants were the Medical Defence Union, represented by Mr. O. Hempson, Lieut.-Colonel George Bidie, who appeared in answer to his notice, was assisted by Mr. Pereira, for the London and Counties Medical Protection Society. Mrs. O'Flynn did not attend, and the Council's solicitor reported that he had been unable to find her address and that she was at that moment seriously ill. The President ordered her name to be struck out of this case.

Mr. O. Hempson said that he proposed to suggest nothing to the detriment of Dr. Bidie, and that his society were merely seeking adjudication. The profession were possibly in doubt as to the proper meaning of the Warning Notice, and the Medical Defence Union had often been consulted on the extent to which a practitioner might associate himself with an institution that attracted patients by means of advertisement, by which he might benefit directly or indirectly. The Medical Defence Union had always held the view that association with an institution providing any kind of medical treatment of the Warning Notice, whether the practitioner received fees for each individual patient or merely profited by the success of the institution.

The "Alpine Sunray Treatment" Clinic, which had been recently formed, had by some extraordinary mischance sent a notice to Mr. Norman King, the Registrar of the Council, at his private address. It consisted of a printed slip entitled on the outside "An Invitation," and contained an account of the foundation of the concern and a laudatory description of its equipment, mentioning also that an experienced consulting physician and a lady doctor were permanently in charge for consultation. It gave a list of the diseases for which artificial sunlight was recommended by the medical profession. The "invitation" was to the recipients and their friends to meet those responsible for the clinic and inspect it, and was clearly from its very form one intended to be received by lay people. Amongst "those responsible" for the conduct of the clinic was, he presumed, Dr. Bidie, as consulting physician. The Registrar had forwarded this pamphlet to the Medical Defence Union, and Mr. Hempson had instructed one of his clerks to write in accordance with the concluding paragraph and ask for the descriptive booklet, which had been received in due course. This had contained the names of the respondent and Mrs. O'Flynn as consultant and assistant physicians, and the manner in which it sought to attract patients to the clinic had been the ground of the present complaint.

Mr. Hempson reviewed the correspondence and interviews which had taken place between the respondent and the Registrar.

According to a letter written on the respondent's instructions by the solicitors to the London and Counties Medical Protection Society, the respondent had, on being approached with an offer of the post of consulting physician, interviewed the Registrar, who had informed him that there was no objection to his taking it provided that he did not circularise or advertise in the public press. Dr. Bidie had received a letter from the managers of the clinic assuring him that their policy would conform to the requirements of the Council, and had thereupon accepted the position, stipulating that he should have an entirely free hand in the selection and retention of the patients and that all nursing and medical matters should be subject to his orders. The patients were to be introduced to him by the secretary and he was then to recommend the appropriate treatment after examination and diagnosis; the secretary was then to make arrangement for treatment and fees. On Sept. 15th Dr. Bidie had received three months' notice on account of the sudden death of the chairman of the institution. He had not been consulted about the framing of the leaflets and pamphlets, but when he had heard of their existence he had approached the managing director and had been assured that none of them were intended for any other purpose than for circulation among the medical profession and personal friends. Dr. Bidie had felt satisfied with this, as he had then no reason to suppose that the assurance he had received, that the concern would conform with the Council's requirements, was not going to be carried out. He had afterwards had doubts about the correctness of the introduction of certain patients, and on writing to the managing director requesting that every patient should be seen by him he had had no reply. The Registrar's letter had been the first intimation respondent had had that circulars were being distributed to the lay public; the London and Counties Medical Protection Society had advised him to dissociate himself from the clinic at once, and this he had done.

A good deal of that letter, said Mr. Hempson, had been written under a misapprehension of the nature of the complaint. The Medical Defence Union were not complaining of respondent's conduct inside the clinic; for all they knew it had been irreproachable. The complaint was against the method by which patients had been attracted to the clinic. The negative attitude the respondent had adopted had not been sufficient. Mr. Hempson submitted, to satisfy his obligations to his profession. The circular had been got up in a form which was almost an insult to the medical profession and most attractive to the layman. He was astounded that the respondent should suggest that it could have any appeal to the profession.

Mr. Hempson then read extracts from the booklet. It began: "This booklet is sent out only in response to inquiries, or the suggestion of someone interested." Those words, presumably put in to anticipate a complaint like the present one, were worthless when

coupled with the wording of the original "invitation"; they were merely a form of special pleading. The clinic was described as the most perfectly equipped in Great Britain; the names of the directors and staff were given, respondent's qualifications and professional history appearing in detail. The authorities quoted were non-medical celebrities, and the public were invited to go to the clinic direct. This was the pamphlet respondent had trustingly accepted as only being circulated to the medical profession and friends of those connected with the clinic, and which had found its way to the Registrar. The Medical Defence Union did not suggest that Dr. Bidie was even aware that that method of advertising was adopted, but submitted that when a medical man joined an institution of this kind he ought to make perfectly certain that nothing of the sort could occur. His duty was an active and not merely a passive one.

Mr. Norman C. King stated in answer to cross-examination that Dr. Bidie had come to see him before accepting the position, and had consulted him about the propriety of taking it. He had replied that there was no objection provided the Council's Warning Notice was not contravened, a slightly wider condition than that of mere abstention from circularising laymen or from advertising in the lay press. He could not recall exactly what he had said to Dr. Bidie, as he had seen other doctors lately on the same subject. He had warned him to be particularly careful with lay people, to see that they carried out their undertakings about advertising. Dr. Bidie could not, he admitted, have done more as a preliminary measure. When asked about the line of demarcation between the practice at such institutions as this and that at certain old-established hydropathic establishments, he said that a person might go to a hydro purely for amusement and change or for convalescence, and it might be very desirable to know that there was a doctor in attendance and who he was. This did not apply to the clinic in question. As far as he knew, the first Dr. Bidie had heard of the complaint was on the day when he had sent a representative to the witness to ask if he might consult him about some difficulties in the administration of the clinic; the letter about the complaints had then been awaiting witness's signature. The witness did not think it within his province to suggest the precautions Dr. Bidie should have taken.

Dr. Bidie, giving evidence on his own behalf, stated that he had served in the Indian Medical Service and had heard of the position at the clinic through a highly placed medical friend, who had put him in touch with the chairman of directors. Immediately after going over the clinic and discussing the matter, he had interviewed the Registrar of the Council, whose evidence concerning the conversation he corroborated. On May 18th he had discussed with the board of directors, before taking the appointment, the safeguards which he had considered proper, telling them that he had seen the Registrar. He had stipulated that there should be no advertising, either to the laity or to the lay press, but had said that they might advertise to the medical profession, or publish a notice about the clinic, possibly even with the names of the medical staff, in medical journals. He had asked for a written assurance that the requirements of the Council should be carried out, and had received a letter from the managing director saying: "We assure you that our policy will conform to all the requirements of the General Medical Council, for we consider that their requirements are in every way proper and in the interests of the public." He had also insisted on complete control over the selection and retention of patients, and over the staff and treatment. He had never seen a copy of the pamphlet which had been delivered at the Registrar's residence, and had never heard of its existence until the Registrar had informed his representative of the complaint at about the end of October. He had only heard of the booklet three to four weeks after the clinic had started, when he had seen the rough draft and photo-

for washing out the bladder (if this were necessary) were obtained. Mr. S. T. Irwin showed radiograms of displacement of the upper epiphysis of the femur in a girl of 11 years and 11 months. Correction of the deformity had been obtained by careful manipulation of the joint, with its immobilisation in plaster for three weeks, and a subsequent period of rest in bed, and the result had been excellent, with only a quarter of an inch shortening of the limb and no deformity visible in the skiagram. Dr. J. T. Lewis reported the case of a man, aged 50, who had marked albuminuria and low blood pressure with normal urea excretion, and who developed jaundice and marked enlargement of the liver with loss of weight. The Wassermann test was found to be positive, and after a course of iodides and novarsenobillon the liver regained its normal size, the jaundice vanished, the albumin almost completely disappeared from the urine, and the systolic blood pressure rose from 90 mm. Hg to 135. Prof. Fullerton, Dr. Marshall, Mr. Crymble, Mr. Irwin, Mr. Purce, Mr. O'Doherty, and Mr. McFadden joined in the discussions following these contributions.

(FROM OUR OWN CORRESPONDENT.)

Matthews Duncan.

At the first sessional meeting of the Edinburgh Obstetrical Society Dr. Haig Ferguson gave a presidential address on Matthews Duncan, his predecessor in the chair in the year 1874. After a vivid recollection of his person, Dr. Ferguson dealt with Duncan's early life, and his outstanding career at Marischal College, Aberdeen, where he carried all before him. His relations with Sir J. Y. Simpson were then alluded to, and emphasis was laid on his intimate connexion with the discovery of chloroform. An accurate account of his valuable publications and addresses was given, and extracts from his diary were read which helped those present to realise what a great man Duncan was and how advanced his ideas were. Edinburgh sustained an irreparable loss when Duncan left to take up his appointment at St. Bartholomew's Hospital. In London he enjoyed a wider sphere of work and had full scope for his marvellous gift of teaching the younger generation. But however busy he was in London, he was never too busy to receive old friends from the North, and to enjoy a crack about Edinburgh affairs. Dr. Ferguson concluded his address by emphasising Duncan's directness and simplicity, upheld by a deeply religious conviction. He was not only one of the most famous gynaecologists but one of the great personalities in medical history.

Heredity and Health.

In one of a series of health lectures promoted by Glasgow Corporation and the Burgh Insurance Committee, Prof. P. E. A. Crow, head of the Animal Research Breeding Department, Edinburgh University, gave a crisp statement of the essential problem. It was important, he said, that a family history should be kept. The question of being well-born was quite important, and having been well-born the next matter was to remain well. Children would not remain well if the environment in which they lived was of a kind that was not conducive to the full expression of their organic inheritance. For every individual exhibiting defect, there were ten carriers. The problem was to identify and cure the carrier, not the defective. It is good that Dr. Crow has put the matter so sharply. At present the carrier of mental defects cannot be diagnosed, except through an exhaustive family history, or through the progeny, or even then the diagnosis can only be a probability. Obviously, if there are ten carriers for one overt defect, segregation of the defective may be advised in the public interest, and as well as in his own. But it is a question of the problem of mental defects. Still less will the elimination of overt defects be the difficulty.

Child Adoption.

The work of the National Children Adoption Association was warmly commended by Lord Murray, of the Court of Session, at the annual meeting of the Scottish Branch of the Association. He was told, he said, that there were people who withheld their sympathy from this work in the belief that they were smoothing the road and making it easier for back-sliders. This was a danger, but they must meet it and beat it. It was some years since he had publicly advocated legalised adoption, and by that he meant that it would be well to have an Act for Scotland similar to the English Statute. In England legislation had, he thought, wisely not gone the whole length. Adoption had been safeguarded and subjected to judicial regulation, but no provision was made in respect of money inheritance and succession, which had hindered the working of the law in France. Lord Murray's commendation comes with force from one who is an authority on the history and evolution of the law of adoption. The Scottish Association, it should be stated, accepts no child on the adoption list without careful examination of its circumstances and suitability. No child is offered for adoption unless it has passed a severe medical examination. No adopters are accepted until they have furnished the Association with two references proving them to be suitable persons to be entrusted with the care of a child. No money passes between the contracting parties, and the two parties are never in direct contact with each other. Even these precautions are not always enough to prevent subsequent trouble and chagrin; but, in the absence of legislation, nothing better seems possible.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Medico-legal Questions.

At a meeting of the Parliamentary Committee for Criminal Reform some members moved that the courts should be authorised to order the sterilisation of habitual criminals, including not only those guilty of sexual crimes, but also those coming from families in which criminality is hereditary. It was stated that in some of the American States sterilisation of criminals is already in operation and that in Denmark introduction of the system is planned. The Minister of Justice spoke against the motion, saying that a professional criminal could not be dismissed even if sterilised, and that the influence of heredity is not yet sufficiently proved to justify such strong measures. A prisoner's agreement to be sterilised as the price of being dismissed from custody could only be regarded as given under duress. The motion was rejected by the committee.

The case is reported in the daily papers of a murderer at Riga who has been sentenced to death and has petitioned for pardon. The Latvian Government, it is said, is inclined to grant the request on condition that he will agree to being inoculated with leprous bacilli for experimental purposes. The report has caused some astonishment in this country, and a Berlin daily paper has asked the opinion of several medical men. Dr. Burger, chief medical officer to the Ministry of Justice, was of opinion that an agreement by a man sentenced to death and hoping to avoid execution by submitting to an experiment which might later lead to severe illness, mutilation, and death under terrible suffering could not be considered as given in full consciousness of his fate, and that the proposal must therefore be condemned. Dr. Hippmann, medical officer to the Magdalen Penitentiary in Berlin, said that the man certainly did not know the sufferings which he might later have to undergo if he agreed to inoculation. It would be against the public spirit of justice to pardon a murderer by replacing capital punishment by a slow but terrible death.

existing examinations. The Council should also consider whether the standard of the examination should not be more clearly defined. For the present, however, the replies were being circulated to the licensing bodies. In May next the Committee proposed to report on how far professional instruction in physics and chemistry in their relation to medicine was being continued throughout the curriculum. After some discussion of detail the report was adopted.

Registration of Indian Students: The Conjoint Board.

In reporting on "Various Matters Remitted to the Education Committee," the President informed the Council that the Conjoint Board in England exempted from pre-registration chemistry and physics those Indian students who could show a pass in the matriculation examination and in the intermediate arts and sciences examination. This enabled them to qualify sooner than their colleagues in India. The Council resolved that the Board be informed that they were not acting in conformity with the requirements of the Council. It was also resolved to inform the Conjoint Board in England that in allowing the medical course to be completed in under five years, they did not satisfy the Council's minimum requirements.

The names of William Birkett, Samuel Theodore Hilton, and Thomas McGowan were restored to the Dental Register.

MEDICINE AND THE LAW.

Death Due to Alcoholism: Reference to Coroner.

DURING an inquest held a few days ago at Westminster Mr. Ingleby Oddie stated that the post-mortem examination had shown the diagnosis to be entirely wrong; death was due to alcoholism. "This is a case," he added, "which should have been reported to me." Deceased was a woman who had lived at an hotel at Monte Carlo until she came to stay at an hotel in the West End of London two months ago. A medical practitioner, giving evidence at the inquest, said he had attended the deceased; he mentioned having called in a second opinion for consultations on two dates in November. Asked by the coroner, "what was the diagnosis?" the witness replied, "I thought latterly she had carcinoma of the liver and heart failure"; he said he knew the deceased was taking alcohol but had never known her take it to excess. "Did not you suspect cirrhosis of the liver?" asked the coroner. "I did," replied the witness, "and I afterwards changed my opinion on clinical grounds." "Why did you not report the case to me?" asked the coroner; "you suspected carcinoma of the liver which was not there; you knew there was cirrhosis, which means drink, and yet you issued a certificate of death without telling me." Later in the case, after a pathologist had described the result of the post-mortem examination and had said that death was due to syncope from cirrhosis brought on by alcohol, the coroner said the law provided that deaths from alcoholism had to be reported to the coroner. This case had not been reported to him and, but for the fact that his officer was an astute officer, the woman would have been buried as having died from carcinoma of the liver.

Mr. Ingleby Oddie is so experienced a coroner that one hesitates to question his observations, if indeed they were correctly reported in this instance. But is it strictly accurate to suggest that a medical practitioner has any obligation to report alcoholism to a coroner? To say to a medical witness, "You issued a certificate of death without telling me," is surely a dubiously phrased complaint. If a practitioner makes an incorrect diagnosis, he cannot escape such blame as the circumstances may warrant. If he knows alcoholism to be a contributory cause of death, he must say so in his certificate. But does the practitioner report directly to the coroner? Regulation 75 of the consolidated code of Regulations dated May 31st, 1927, deals with the cases in which reference must be made to the coroner. One of these is that of

"any death which appears to the registrar from the contents of the medical certificate to have been due to . . . alcoholic poisoning." But it is the registrar who refers the case to the coroner. Mr. Ingleby Oddie is, of course, entitled to point out that, because the medical practitioner in the instance under discussion failed to name alcoholic poisoning as a cause or contributory cause of death, therefore the registrar was unable to report the case to the coroner under Regulation 75. Was Mr. Oddie referring to this Regulation? If so, it should perhaps be made plain that the deceased's medical attendant had a duty to certify the cause of death but no duty to report to the coroner.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Medical Certification of Insured Persons.

ON Nov. 30th General R. Mulcahy, Minister for Local Government and Public Health, received a deputation which had been appointed by the Irish Medical Committee to discuss with him the proposal recently made by the National Health Insurance Commission to change the pool area of distribution of remuneration for medical certification from the dispensary district to the county. The deputation, which consisted of Drs. T. Hennessy, R. J. Rowlette, H. J. Raverty, and J. P. Shanley, put before the Minister the reasons which led the committee to decline to recommend the proposal of the National Health Insurance Commission for acceptance by the certifiers. After a long discussion the Minister agreed to defer any change in the present mode of payment until he had had time further to consider the present system as compared with alternatives which might possibly be more administratively sound and more equitable to the certifiers. He commented on the present cost of distributing the £37,000 for medical certification. The cost to the State of medical certification was, he said, one-tenth of the total inclusive cost to the State of National Health Insurance and its administration.

Ulster Medical Society.

The third meeting of the session was held in Belfast on Nov. 29th, with Prof. T. H. Milroy, the President, in the chair. Dr. J. A. Smyth read notes on some interesting cases of nephritis. The first was one which clinically resembled Addisonian anaemia, and showed no definite oedema and only a trace of albumin in the urine. The diagnosis was made by finding that the chloride excretion had fallen to 0.3 g., and post-mortem findings were typical of hydræmic nephritis. The second case was that of a man who died in uræmic coma with a blood-urea content of 363 mg. per cent. and a blood creatinine of 8 mg. per cent., without having any albumin in his urine during the week before death while under observation. A photograph was shown of a man who, in appearance, presented the typical features of hydræmic nephritis, but on examination proved to have nephritis of pure azotæmic type. Dr. Smyth next showed a curve illustrating a marked fall in blood-urea (from 353 to 72 mg. per cent.) in a case of enlarged prostate following the use of a tied-in catheter. A notable feature was the almost negligible fall in blood creatinine, from 5.2 to 4.6 mg. per cent., despite marked improvement in the patient's clinical condition. The last case was that of a woman suffering from a mixed type of nephritis, who had been under observation for three and a half years. At the beginning of this period she had definite albuminuric retinitis which afterwards cleared up; pregnancy caused a considerable further failure of renal functions, which improved on the induction of labour.

Prof. Andrew Fullerton demonstrated by means of anatomical diagrams his method of perineal drainage of the bladder after suprapubic prostatectomy, showing that no injury was caused to the levator ani muscle, while adequate drainage and the ideal route

for washing out the bladder (if this were necessary) were obtained. Mr. S. T. Irwin showed radiograms of displacement of the upper epiphysis of the femur in a girl of 11 years and 11 months. Correction of the deformity had been obtained by careful manipulation of the joint, with its immobilisation in plaster for three weeks, and a subsequent period of rest in bed, and the result had been excellent, with only a quarter of an inch shortening of the limb and no deformity visible in the skiagram. Dr. J. T. Lewis reported the case of a man, aged 50, who had marked albuminuria and low blood pressure with normal urea excretion, and who developed jaundice and marked enlargement of the liver with loss of weight. The Wassermann test was found to be positive, and after a course of iodides and novarsenobillon the liver regained its normal size, the jaundice vanished, the albumin almost completely disappeared from the urine, and the systolic blood pressure rose from 90 mm. Hg to 135. Prof. Fullerton, Dr. Marshall, Mr. Crymble, Mr. Irwin, Mr. Purce, Mr. O'Doherty, and Mr. McFadden joined in the discussions following these contributions.

Medico-legal Questions.

At a meeting of the Parliamentary Committee for Criminal Reform some members moved that the courts should be authorised to order the sterilisation of habitual criminals, including not only those guilty of sexual crimes, but also those coming from families in which criminality is hereditary. It was stated that in some of the American States sterilisation of criminals is already in operation and that in Denmark introduction of the system is planned. The Minister of Justice spoke against the motion, saying that a professional criminal could not be dismissed even if sterilised, and that the influence of heredity is not yet sufficiently proved to justify such strong measures. A prisoner's agreement to be sterilised as the price of being dismissed from custody could only be regarded as given under duress. The motion was rejected by the committee.

The case is reported in the daily papers of a murderer at Riga who has been sentenced to death and has petitioned for pardon. The Latvian Government, it is said, is inclined to grant the request on condition that he will agree to being inoculated with leprosy bacilli for experimental purposes. The report has caused some astonishment in this country, and a Berlin daily paper has asked the opinion of several medical men. Dr. Burger, chief medical officer to the Ministry of Justice, was of opinion that an agreement by a man sentenced to death and hoping to avoid execution by submitting to an experiment which might later lead to severe illness, mutilation, and death under a terrible suffering could not be considered as given in full consciousness of his fate, and that the proposal must therefore be condemned. Dr. Heppmann, medical officer to the Morbit Penitentiary in Riga, said that the man certainly did not know the sufferings which he might later have to undergo if he agreed to inoculation. It would be against the public spirit of justice to pardon a murderer by replacing capital punishment by a slow but terrible death.

The Morphia Habit.

In one of the Parliamentary Committees a question has been put to the Government as to whether the morphia habit is increasing in Germany. A representative of the Health Office states in reply that for every 100,000 of the population three men and one woman are known to indulge in the habit. The number of patients treated in hospitals and sanatoriums for this condition was 1497 in the period 1911-13, 3084 in 1920-22, 1283 in 1923, and 1623 in 1925. The number of deaths attributed to this form of intoxication was 32 in 1923, 18 in 1924, and 39 in 1925. A total of 2400 kg. of alkaloid imported into Germany is compared with an export of 9520 kg. during the same period, and the question has been raised whether its production should not be limited to the amount consumed. To this suggestion the Government spokesman replied that there is a great need of alkaloids throughout the world, and that only a few countries produced them—namely, Great Britain, Switzerland, France, Germany, and Japan. The matter is regulated by international conventions which make it illegal to use them for purposes other than the strictly medical. The committee eventually adopted a motion that the Government should consider measures to limit the production of alkaloids to the quantity necessary for medical purposes in Germany.

SHOT IN THE VERMIFORM APPENDIX.

To the Editor of THE LANCET.

SIR,—I have read with much interest the case reported in your last issue by Prof. John Fraser, together with his valuable comments thereon. It has for many years been my practice to remove the appendix in practically every abdominal section I perform for non-urgent conditions, and afterwards to slit it up for examination. On only four occasions have I met with shot in the appendix, and in only one of these had the condition been suspected prior to operation. This was in a youth of 20, who after spending five weeks shooting on his father's estate in Scotland and living largely on game, developed some vague abdominal discomfort for which his medical adviser ordered him to be radiographed. The radiographer reported that there were 15 pellets in the appendix; a second radiogram ten days later showed only nine. Although it was considered quite likely that the pellets might be passed naturally, yet as the youth was about to take up residence abroad appendectomy was decided upon, and two days later I removed the appendix. It contained nine pellets at its distal end, the mucosa at this region being very definitely reddened; otherwise the appendix was normal, and was free from adhesion.

A consideration of the enormous amount of shot game that is annually consumed suggests that the entry of pellets in the appendix is not a very rare occurrence, and that most of them ultimately escape therefrom and are passed naturally.

I am, Sir, yours faithfully,

Manchester, Dec. 3rd, 1925.

ARTHUR H. BURGESS.

To the Editor of THE LANCET.

SIR,—The clinical notes of Prof. Fraser recall a case I saw, I think it was in 1913, of a locally well-known sportsman whose shoot was near Edenbridge in Kent, from whose appendix some 24 shot were removed at an operation by Mr. J. B. Footner, of Tunbridge Wells.—I am, Sir, yours faithfully,

F. THOMPSON, M.R.C.S., L.R.C.P.

Epsom, Dec. 3rd, 1925.

A TUDOR ACT OF INDEMNITY FOR UNQUALIFIED PRACTICE.

To the Editor of THE LANCET.

SIR,—The principal interest attaching to the document found at New Romney is the question of its authenticity. It does not ring true. At no time, so far as is known, has it been possible to inhibit the medical practice of "divers honest persons . . . whom God hath endued with the knowledge. . . . Medical faculties possessed of extreme repressive powers, even ecclesiastical authorities, have tried in vain to do so. If, then, Henry VIII. found it necessary to protect the self-constituted practitioners of medicine, his Statute must be unique.

The knowledge of the existence of such a document is, however, an old story. Sir D'Arcy Power must have had it before him, in whole or part, 40 years ago, for he quotes some sentences verbatim from it in his "Memorials of the Craft of Surgery" (Casell and Co., 1886). It is right to add that though he gives no reference to an authority, he appears to accept the document as genuine. The "customable diseases" are, also, well known. "A pin and the webbe in the eye" very commonly go together. Thus Leontes in "A Winter Tale" speaks of "all eyes Blind with the pin and web but theirs." Pin or pane or panne (from *pannus*, a cloth or web) refers

How can we find out if they are?

upon to treat? Moreover, it is not possible to get young children to sit up in a chair and submit to such a procedure. The first point calls for the establishment of many more special throat hospitals. To the second point I reply, if all authorities are unanimous in regarding the tonsil as a protective organ in childhood, why remove it? Treatment of enlarged tonsils should be deferred until the child has reached such an age as to permit the cautery to be used. In the meantime endocrine medication is valuable. The effect of small doses of thyroid, given over a period of months, is astonishing in children showing marked ill-development and malnutrition.

I repudiate any suggestion that I am trying to teach throat specialists their business, but I submit that an experienced general physician is better informed as to the causes, effects, and treatment of chronic sepsis and hypertrophy of the tonsils. I plead for the more frequent use of the cautery in tonsillar disease. It leaves no raw surface; it causes no bleeding; it leaves a portion of the tonsil behind to continue its function, and it does not damage the capsule which guards the peritonsillar area from that dangerous septic infection which may occur after tonsillectomy.—I am, Sir, yours faithfully,

Harley-street, W., Dec. 1st.

W. S. WHITCOMBE.

CHRONIC SPASMODIC AFFECTIONS OF THE COLON.

To the Editor of THE LANCET.

SIR,—The admirable and important lecture by Dr. Ryle that appeared in your columns last week deals with a difficult subject of great interest in a lucid and compendious fashion that places us all under obligation to him. But I cannot help feeling that the ultimate issue of Dr. Ryle's observations, anticipated in almost every paragraph of the address, is given in the sentence that declares psychotherapy to play an important part in the treatment of spasticity of the colon and mucous colitis. I would go a little farther, and say that psychotherapy plays an indispensable part, provided that it is undertaken by the general physician or practitioner who controls the physical therapy as well.

As a matter of fact, like, I suppose, many others, I have been accustomed for some years past, both in practice and in teaching, to state the view—well-founded, I believe—that spasticity of the colon and mucous colitis should be looked upon as visceral expressions of emotional or affective states, that seize upon an "organ-inferiority" as giving the line of least resistance to what is sometimes called a "get-out." The emotional state of which the tension is thus somewhat eased may not always be a quite normal emotional state, nor occurring under quite normal circumstances in a quite normal person. As much may be said about the emotional states that lead to weeping—a pretty familiar "visceral" expression of an affective state. However, the phraseology of the Old Testament should convince us that, in former times, the expression of emotion by bowel states was familiar. It certainly was during the war. But the state of emotional or affective tension that is responsible for spasticity of the colon, or mucous colitis, is not always the superficial and obvious "worry" or the like, of which the patient is sometimes, if not always, the subject. It is sometimes deeper, something repressed, and at first not known, consciously, or not recognised by the patient. It arises always, I think, from a difficulty in relation to sexual life or adjustment.

How this may be we can perhaps imagine if we look at any modern diagram of the vegetative nervous systems, when we see that the colon, but *not* the small intestine, is functionally associated, or represented, in the "sacral autonomic" with the pelvic organs, in either sex. This fact explains, *inter alia*, why gynaecologists so commonly find some "pelvic trouble" in the mucous colitis cases. But the "trouble" is not the whole cause of the affection; it is the organ-inferiority which may sometimes

provoke the emotional state, in some degree, sometimes, and, otherwise, may be a secondary event, consequent upon the emotional difficulty or conflict. To remove the uterus or appendages, or to resect the colon, in these cases—as often has been done—is as foolish as to take off the telephone receiver to avoid getting rung up on a "wrong number" call.

In alluding to the almost invariable origin of the emotional stress in some sexual relation, I do not, of course, mean to suggest that the cure for spasticity of the colon or of mucous colitis is to be found in sexual indulgence. But I do suggest that, if the patient's inner conflict is made clear to him, and an adjustment is achieved, by sublimation or otherwise, then, if such wise therapeutic measures as those recommended by Dr. Ryle are instituted, the patient gets well. If his whole life-scheme, and not merely the problem of the moment, be adjusted, he or she *keeps well*.

Finally, I would agree absolutely with Dr. Ryle in saying that there is a relation or connexion between spastic colon and migraine. The same kind of people, acting in the same kind of way under stress or in conflict, suffer from these affections. But, if in spastic colon and mucous colitis we have to do with an affection whose physical mechanism is that of the sacral autonomic, in migraine, surely, we are concerned with the oculomotor and, sometimes, the vagal parts of the cranial autonomic system or systems. Here the common organ-inferiority is in respect of the eye, and the trouble is far less exclusively sexual than in the case of the colon and its neuroses. But, in both cases, in both sets of cases, the "thorough understanding" for which Dr. Ryle asks, by way of diagnosis, can only come when the patient's condition is individualised. It escapes us when it is "typed."—I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 30th. F. G. CROOKSHANK.

SMOKELESS FUEL AND PUBLIC HEALTH.

To the Editor of THE LANCET.

SIR,—We, the undersigned medical officers of health, desire to draw attention to the fact that the Public Health (Smoke Abatement) Act, 1926, now being applied in various areas, is by itself inadequate to deal with the serious consequences to public health of atmospheric pollution—due mainly to the burning of raw coal—inasmuch as it deals solely with the emission of industrial smoke.

Atmospheric impurities are undoubtedly directly responsible in a wide measure for pulmonary diseases, and indirectly, by reducing sunshine, for diseases peculiar to childhood (notably rickets), as well as for a general lowering of national vitality. This deplorable state of affairs cannot be remedied until practical steps on a large scale are taken to deal with the all-important problem of domestic smoke.

We desire to endorse the opinion expressed by Sir George Newman, chief medical officer of the Ministry of Health, in his annual report for 1925, that

"Every form of industrial or mechanical contrivance which either prevents or reduces pollution of the atmosphere is a contribution to the public health, and this aspect of the problem calls for the continued and vigilant attention both of authorities and those responsible for commercial concerns."

For the foregoing reason we are of opinion that the Government and local authorities should not only encourage the wider adoption of existing smokeless fuels in common use, such as gas and electricity, but should also, by educational methods or the creation of local supplies, endeavour to secure the general use of solid smokeless fuels, such as those derived from low temperature carbonisation.

We cannot associate ourselves with the view that commercial production of smokeless fuels by low temperature carbonisation has not yet been reached, inasmuch as various types of such fuels are now actually available to the public; on the contrary, we wish to record our conviction that a substantial reduction of domestic smoke and consequent improve-

ment of national health and physique would result if the appropriate Government departments and local authorities officially recognised and encouraged the wider production and use of the smokeless fuels that are now being marketed by British enterprise.

We are, Sir, yours faithfully,

ULTRA-VIOLET LIGHT AND CANCER.

To the Editor of THE LANCET.

SIR.—Dr. Findlay's paper in your issue of Nov. 24th is of such vast importance, both to the public and to actinotherapists, that one is compelled to ask the author for his views on the following points which arise from his work.

1. In his review of the literature, the terms "weather," "solar rays," and "sunlight" are used synonymously, but the author incriminates the ultra-violet portion of these rays only.

2. To prove the effect of sunlight experimentally, a mercury-vapour lamp was used. The spectrum of the mercury-vapour lamp bears little resemblance to that of sunlight. It is quite impossible to say whether the rays of the lamp below 2950 A.U., which do not occur in sunlight, or those above 2950 A.U., were responsible for the tumour formation.

3. The dose is expressed in terms of time and distance and not in terms of erythema. Assuming that the burner was a new one, two minutes at 18 in. would have caused a marked erythema on the average human skin. This dose was administered four times a week. What degree of erythema did this produce on the mice? Ulceration was mentioned in Experiment 3, where the dose was even heavier than the above. Was there any relation between the ulceration and subsequent formation of growth?

4. Did the animals establish any tolerance to the dose? The average human skin would rapidly have established its own protection by the formation of pigment. Although, with the dose administered to the mice, the human skin would have shown a marked erythema at first, subsequent doses repeated four times a week would have had no effect. In the albino mice, on the contrary, every dose probably served as a new irritant.

5. Could experiments be carried out interposing a Pyrex filter to cut out the rays below 2950 A., and measuring the time of exposure so that the dose would correspond to a first degree erythema on human skin?

6. Could similar experiments be carried out using fluorescent light bulbs instead of the mercury-vapour lamp?

7. The authorities quoted certainly are in favour of the ultra-violet rays playing an important part in the causation of cancer on exposed surfaces which I have been unable to mention of the causation by heat, carrying notions of the drivers of the car.

vincing if the term infra-red were substituted for ultra-violet.

9. Until it has been demonstrated that infra-red rays cannot produce cancer under similar conditions, it is doubtful whether he is justified in assuming that his experiments support the ultra-violet hypothesis.

The points raised in no way detract from the value of Dr. Findlay's demonstration that the mercury vapour spectrum under certain conditions may produce cancer. The observation is of the utmost significance and will do a great deal towards rescuing ultra-violet therapy from its present unsatisfactory position.

I am, Sir, yours faithfully,

London, W., Dec. 1-4, 1928.

IMPERIAL CANCER RESEARCH FUND.

A MEETING of the General Committee was held at St. Queen's-square, London, W.C., on Nov. 25th, the Duke of Bedford presiding. Sir Humphry Rolleston, as chairman of the Executive Committee, moved the adoption of the twenty-sixth annual report of the Fund for the year 1927-28, and summarised the report of the director, on which we have already commented (THE LANCET, Dec. 1st, 1928, p. 1137). He spoke also of the wide range of the activities of the Fund during the 25 years of its existence. A store of knowledge had been gained which made it possible to judge the validity of statements published by individual workers. During the past year a surgeon of repute presented at a surgical congress in Germany the results of a prolonged and extensive investigation in which he claimed to have proved the transmission of human cancer to mice in such a way that the infective nature of cancer was thereby established. If such a conclusion were justified it would mean a complete revolution in our conception of the nature of the disease and also in its treatment; but it would also create great alarm among the general public, and especially among those who have relatives suffering from cancer. Fortunately, the data collected in the laboratories of the Fund concerning the frequency with which cancer naturally affects mice throughout the whole course of their lives, made it possible to state definitely that in these experiments the human cancer was not transmitted to mice. Sir Humphry Rolleston referred to the zeal and patience of Dr. J. A. Murray, the director, and his staff, and congratulated the committee on having been able to enlist and the services of men who were willing and able to elaborate and difficult experiments from year to year. The resolution was seconded by Sir D'Arcy carried unanimously. The President, in thanking the officers, drew attention taken by the profession and the public of cancer, which overshadowed the International Conference and of the detailed statistical issued during the last of the Ministry of practical problems they give but a glimpse of the

upon to treat? Moreover, it is not possible to get young children to sit up in a chair and submit to such a procedure. The first point calls for the establishment of many more special throat hospitals. To the second point I reply, if all authorities are unanimous in regarding the tonsil as a protective organ in childhood, why remove it? Treatment of enlarged tonsils should be deferred until the child has reached such an age as to permit the cautery to be used. In the meantime endocrine medication is valuable. The effect of small doses of thyroid, given over a period of months, is astonishing in children showing marked ill-development and malnutrition.

I repudiate any suggestion that I am trying to teach throat specialists their business, but I submit that an experienced general physician is better informed as to the causes, effects, and treatment of chronic sepsis and hypertrophy of the tonsils. I plead for the more frequent use of the cautery in tonsillar disease. It leaves no raw surface; it causes no bleeding; it leaves a portion of the tonsil behind to continue its function, and it does not damage the capsule which guards the peritonsillar area from that dangerous septic infection which may occur after tonsillectomy.—I am, Sir, yours faithfully,

Harley-street, W., Dec. 1st.

W. S. WHITCOMBE.

CHRONIC SPASMODIC AFFECTIONS OF THE COLON.

To the Editor of THE LANCET.

SIR,—The admirable and important lecture by Dr. Ryle that appeared in your columns last week deals with a difficult subject of great interest in a lucid and compendious fashion that places us all under obligation to him. But I cannot help feeling that the ultimate issue of Dr. Ryle's observations, anticipated in almost every paragraph of the address, is given in the sentence that declares psychotherapy to play an important part in the treatment of spasticity of the colon and mucous colitis. I would go a little farther, and say that psychotherapy plays an indispensable part, provided that it is undertaken by the general physician or practitioner who controls the physical therapy as well.

As a matter of fact, like, I suppose, many others, I have been accustomed for some years past, both in practice and in teaching, to state the view—well-founded, I believe—that spasticity of the colon and mucous colitis should be looked upon as visceral expressions of emotional or affective states, that seize upon an "organ-inferiority" as giving the line of least resistance to what is sometimes called a "get-out." The emotional state of which the tension is thus somewhat eased may not always be a quite normal emotional state, nor occurring under quite normal circumstances in a quite normal person. As much may be said about the emotional states that lead to weeping—a pretty familiar "visceral" expression of an affective state. However, the phraseology of the Old Testament should convince us that, in former times, the expression of emotion by bowel states was familiar. It certainly was during the war. But the state of emotional or affective tension that is responsible for spasticity of the colon, or mucous colitis, is not always the superficial and obvious "worry" or the like, of which the patient is sometimes, if not always, the subject. It is sometimes deeper, something repressed, and at first not known, consciously, or not recognised by the patient. It arises always, I think, from a difficulty in relation to sexual life or adjustment.

How this may be we can perhaps imagine if we look at any modern diagram of the vegetative nervous systems, when we see that the colon, but not the small intestine, is functionally associated, or represented, in the "sacral autonomic" with the pelvic organs, in either sex. This fact explains, inter alia, why gynaecologists so commonly find some "pelvic trouble" in the mucous colitis cases. But the "trouble" is not the whole cause of the affection; it is the organ-inferiority which may sometimes

provoke the emotional state, in some degree, sometimes, and, otherwise, may be a secondary event, consequent upon the emotional difficulty or conflict. To remove the uterus or appendages, or to resect the colon, in these cases—as often has been done—is as foolish as to take off the telephone receiver to avoid getting rung up on a "wrong number" call.

In alluding to the almost invariable origin of the emotional stress in some sexual relation, I do not, of course, mean to suggest that the cure for spasticity of the colon or of mucous colitis is to be found in sexual indulgence. But I do suggest that, if the patient's inner conflict is made clear to him, and an adjustment is achieved, by sublimation or otherwise, then, if such wise therapeutic measures as those recommended by Dr. Ryle are instituted, the patient gets well. If his whole life-scheme, and not merely the problem of the moment, be adjusted, he or she keeps well.

Finally, I would agree absolutely with Dr. Ryle in saying that there is a relation or connexion between spastic colon and migraine. The same kind of people, acting in the same kind of way under stress or in conflict, suffer from these affections. But, if in spastic colon and mucous colitis we have to do with an affection whose physical mechanism is that of the sacral autonomic, in migraine, surely, we are concerned with the oculomotor and, sometimes, the vagal parts of the cranial autonomic system or systems. Here the common organ-inferiority is in respect of the eye, and the trouble is far less exclusively sexual than in the case of the colon and its neuroses. But, in both cases, in both sets of cases, the "thorough understanding" for which Dr. Ryle asks, by way of diagnosis, can only come when the patient's condition is individualised. It escapes us when it is "typed."—I am, Sir, yours faithfully,

Wimpole-street, W., Nov. 30th. F. G. CROOKSHANK.

SMOKELESS FUEL AND PUBLIC HEALTH.

To the Editor of THE LANCET.

SIR,—We, the undersigned medical officers of health, desire to draw attention to the fact that the Public Health (Smoke Abatement) Act, 1926, now being applied in various areas, is by itself inadequate to deal with the serious consequences to public health of atmospheric pollution—due mainly to the burning of raw coal—inasmuch as it deals solely with the emission of industrial smoke.

Atmospheric impurities are undoubtedly directly responsible in a wide measure for pulmonary diseases, and indirectly, by reducing sunshine, for diseases peculiar to childhood (notably rickets), as well as for a general lowering of national vitality. This deplorable state of affairs cannot be remedied until practical steps on a large scale are taken to deal with the all-important problem of domestic smoke.

We desire to endorse the opinion expressed by Sir George Newman, chief medical officer of the Ministry of Health, in his annual report for 1925, that

"Every form of industrial or mechanical contrivance which either prevents or reduces pollution of the atmosphere is a contribution to the public health, and this aspect of the problem calls for the continued and vigilant attention both of authorities and those responsible for commercial concerns."

For the foregoing reason we are of opinion that the Government and local authorities should not only encourage the wider adoption of existing smokeless fuels in common use, such as gas and electricity, but should also, by educational methods or the creation of local supplies, endeavour to secure the general use of solid smokeless fuels, such as those derived from low temperature carbonisation.

We cannot associate ourselves with the view that commercial production of smokeless fuels by low temperature carbonisation has not yet been reached, inasmuch as various types of such fuels are now actually available to the public; on the contrary, we wish to record our conviction that a substantial reduction of domestic smoke and consequent improve-

ment of national health and physique would result if the appropriate Government departments and local authorities officially recognised and encouraged the wider production and use of the smokeless fuels that are now being marketed by British enterprise.

We are, Sir, yours faithfully,

ULTRA-VIOLET LIGHT AND CANCER.

To the Editor of THE LANCET.

SIR,—Dr. Findlay's paper in your issue of Nov. 24th is of such vast importance, both to the public and to actinotherapists, that one is compelled to ask the author for his views on the following points which arise from his work.

1. In his review of the literature, the terms "weather," "solar rays," and "sunlight" are used synonymously, but the author incriminates the ultra-violet portion of these rays only.

2. To prove the effect of sunlight experimentally, a mercury-vapour lamp was used. The spectrum of the mercury-vapour lamp bears little resemblance to that of sunlight. It is quite impossible to say whether the rays of the lamp below 2950 A.U., which do not occur in sunlight, or those above 2950 A.U. were responsible for the tumour formation.

3. The dose is expressed in terms of time and distance and not in terms of erythema. Assuming that the burner was a new one, two minutes at 18 in. would have caused a marked erythema on the average human skin. This dose was administered four times a week. What degree of erythema did this produce on the mice? Ulceration was mentioned in Experiment 3, where the dose was even heavier than the above. Was there any relation between the ulceration and subsequent formation of growth?

4. Did the animals establish any tolerance to the dose? The average human skin would rapidly have established its own protection by the formation of pigment. Although, with the dose administered to the mice, the human skin would have shown a marked erythema at first, subsequent doses repeated four times a week would have had no effect. In the albino mice, on the contrary, every dose probably served as a new irritant.

5. Could experiments be carried out interposing a Uviol filter to cut out the rays below 3000 A. and increasing the time of exposure so that the dose would correspond to a first degree erythema on human skin?

6. Could similar experiments be carried out using 1000-1500-watt radiant heat bulb (glass) so that the effect of the visible rays and infra-red could be estimated?

7. The authorities quoted certainly appear to make a good case in favour of the hypothesis that ultra-violet rays play an important part in the development of cancer on exposed skin. In those of his references which I have been able to consult there is, however, no mention of the skin cancer presumably due to irritation by heat, such as cancer in the kangaroo-carrying natives of Kashmir or the cancer on the skins of engine-drivers.

8. With the latter types in mind, the papers of some of his authorities would have been equally con-

vincing if the term infra-red were substituted for ultra-violet.

9. Until it has been demonstrated that infra-red rays cannot produce cancer under similar condition, it is doubtful whether he is justified in assuming that his experiments support the ultra-violet hypothesis.

The points raised in no way detract from the value of Dr. Findlay's demonstration that the mercury-vapour spectrum under certain conditions may produce cancer. The observation is of the utmost significance and will do a great deal towards rescuing ultra-violet therapy from its present unsatisfactory position.

I am, Sir, yours faithfully,

London, W., Dec. 1st, 1928.

M. WEINBREN.

Dr. Percy Hall writes to say that he has entirely severed his connexion with National Sun Ray and Health Centres, Ltd.

IMPERIAL CANCER RESEARCH FUND.

A MEETING of the General Committee was held at 8, Queen-square, London, W.C., on Nov. 28th, the Duke of Bedford presiding. Sir Humphry Rolleston, as chairman of the Executive Committee, moved the adoption of the twenty-sixth annual report of the Fund for the year 1927-28, and summarised the report of the director, on which we have already commented (THE LANCET, Dec. 1st, 1928, p. 1137). He spoke also of the wide range of the activities of the Fund during the 25 years of its existence. A store of knowledge had been gained which made it possible to judge the validity of statements published by individual workers. During the past year a surgeon of repute presented at a surgical congress in Germany the results of a prolonged and extensive investigation in which he claimed to have proved the transmission of human cancer to mice in such a way that the infective nature of cancer was thereby established. If such a conclusion were justified it would mean a complete revolution in our conception of the nature of the disease and also in its treatment; but it would also create great alarm among the general public, and especially among those who have relatives suffering from cancer. Fortunately, the data collected in the laboratories of the Fund concerning the frequency with which cancer naturally affects mice throughout the whole course of their lives, made it possible to state definitely that in these experiments the human cancer was not transmitted to mice. Sir Humphry Rolleston referred to the zeal and patience of Dr. J. A. Murray, the director, and his staff, and congratulated the committee on having been able to enlist and retain the services of men who were willing and able to pursue elaborate and difficult experiments from year to year. The resolution was seconded by Sir D'Arcy Power, and carried unanimously. The President, in moving a resolution thanking the officers, drew attention to the keen interest taken by the profession and the public in the clinical aspects of cancer, which overshadowed all others at the recent International Conference and constituted the mainspring of the detailed statistical reports on cancer of certain sites issued during the last few years by the Cancer Committee of the Ministry of Health. But, he said, these immediate practical problems of the treatment of cancer could of necessity give but little information on the more fundamental problems of the disease. The Imperial Cancer Research Fund was established with the intention of providing, by an adequate endowment, for continuous work into the problem of the nature and causation of cancer. That the methods of investigation adopted by the Fund 26 years ago were right might be gathered from the fact that they had been adopted all over the world by institutions devoted to the study of cancer. The additions to knowledge made by the experimental method were so great that it is difficult to conceive how the present state of knowledge could have been acquired in any other way. At the same time unsuspected difficulties and intricacies had emerged, and the necessity for the most critical examination of many supposed advances was great. The extent to which present methods of treatment were rational could best be appraised by experimental investigation of results under the controlled conditions of the laboratory.

Sir Basil Mayhew was elected a Vice-President of the Fund. Prof. A. E. Boycott and Prof. William Bulloch were re-elected members, and Sir Thomas Barlow and Sir Anthony Bowlby additional members, of the Executive Committee.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT BILL.

In the House of Commons on Monday, Tuesday, and Wednesday, Nov. 26th, 27th, and 28th, the debate was resumed on the Local Government Bill.

Following the speech by Mr. NEVILLE CHAMBERLAIN, Minister of Health, in moving the second reading, which was reported in our last issue:

Official Labour Amendment.

Mr. ARTHUR GREENWOOD moved the following amendment on behalf of the Labour Party:—

This House declines to assent to the Second Reading of a Bill which, whilst amending the law relating to poor relief, perpetuates the evils of the poor-law system and extends the vicious practice of unrepresentative persons being nominated to membership of elected bodies, makes no provision for the prevention of destitution, fails to make unemployment a national responsibility, and will not appreciably relieve the financial position of necessitous areas; will arrest the normal and steady development of local health services by the establishment of fixed block grants from the Exchequer and the imposition of a charge for treatment in hospitals, especially maternity hospitals, a proposal calculated to increase the already high mortality amongst mothers; inaugurates a system of rating relief that will be unfair in its incidence; and, by failing adequately to reimburse local authorities for loss of revenue, will add to the burdens of shopkeepers, householders, and other ratepayers.

He said that he was a strong opponent of the Bill. The block grant was really a device for saving the money of the taxpayer; if it did not do that it failed in its purpose. If block grants meant the bringing together of cognate and allied services there might be something to be said for them. But where they consisted in bringing together services which had absolutely no relation to one another the results were bound to be absurd. He believed that if they stabilised the grant for five years they could not help impeding the development of the health services. It meant that the additional expenditure would have to be borne entirely out of the rates, or that additional expenditure would be put aside and the service would not be developed. Since 1909, when the Royal Commission on the Poor-law reported, the Labour Party had been pledged to the abolition of the board of guardians and the poor-law system as they knew it. Under this Bill the poor-law system remained as firmly established as ever. It was still a deterrent system which discouraged people in their trouble from going to the poor-law authorities. A proportion of non-elected persons who knew the ropes of the game were the persons who were going to run the guardians' committee, and not the directly elected representatives from the county or county district areas. He looked with great apprehension on the new proposal about compulsory powers to be exercised by local authorities to demand payment in respect of certain health services. The Minister admitted that in the case of infectious diseases it was very necessary that persons suffering from them should be taken into hospitals. It was equally necessary for the good of the community that the expectant mother should receive treatment, and that women with cancer should have radiological treatment, without necessarily having to make payment. This must injure the health services of the country. The energies of the local authorities would be absorbed in making inquiries and collecting money instead of being devoted to rooting out diseases and discovering their causes. The Bill was going to make serious inroads into the independence of the local governing bodies. By concentration of power in the hands of counties and county boroughs the Government were delivering a smashing blow at all the non-county boroughs, the large urban districts which were efficiently administered to-day, and whose powers might admirably have been extended.

Mr. DUNNICO, in seconding the amendment, said that the effect of the block grant would be to destroy initiative and to prevent advanced local authorities from undertaking work which in normal conditions they would be glad to do. The maternity and child welfare movement should be greatly developed in the future, but the block grant would kill and stop its development. The Government, under the Bill, were making it compulsory on local authorities to sue in the county court mothers who had gone into maternity homes, yet in the same clause they excused those who sought treatment for infectious diseases and venereal disease.

Mr. R. HUDSON said if there was one thing that the Bill was calculated to do it was to decrease maternal mortality by making available to women all over the country accommodation in institutions under the control and care of the county councils—accommodation which had hitherto been reserved exclusively for the destitute poor, and, therefore, but meagrely taken advantage of. When institutions

were dealt with as proposed in the Bill, it would be possible for the county council for the first time seriously to tackle the disquieting increase in the rate of maternal mortality.

Mr. ERNEST BROWN, who spoke for the Liberal Party, said that one of his reasons for objecting to the Bill was that he could not see how they could combine the idealistic conception of a great extension of medical services under one control with the reactionary and retrogressive financial scheme of block grants, or how they could provide for its expansion. It was incontrovertible that had the block grant system prevailed during the past 25 years instead of the "fifty-fifty" system there would have been a far smaller extension in those services than there had been. As regarded the poor-law, the scheme in his judgment did not propose to carry out an efficient distribution of poor-law duties, the appointed bodies proposed would not function so well as the elected bodies which they superseded, and the wealth of talent for administration among women would find no adequate outlet as it had done through the boards of guardians. The gravest of all difficulties in Part I. of the Bill was that it shirked the issue of the able-bodied poor.

Mr. SCURR complained of the clause which made it compulsory for county and county borough councils to levy charges on persons who would receive assistance in the shape of medical treatment. He was concerned with the prevention and cure of disease, and he held that it should not be a question of whether a patient was in a position to pay or not but whether he or she needed treatment.

Sir HENRY SLESSER said this measure in no wise humanised or altered the existing poor-law. Since the Poor Law Act of 1834 one authority after another had been appointed by the State for the purpose of relieving the various distressed persons—the education authority, the health authority, the lunacy authority, the mental defective authority, and many others—for dealing with the very matters which used to be within the province of the old poor-law. Therefore, the continuation of the old poor-law was on all sides, he thought; admitted to be unjustifiable, wasteful, cruel, and useless. Yet as regards the poor-law this Bill did nothing of value, and what it did was reactionary and detrimental.

Medical Views.

Lieut.-Colonel FREMANTLE called attention to what he regarded as the most authoritative announcement that had yet been made by the medical profession. It was the considered statement of the British Medical Association Poor-law Relief Committee, whose conclusion was on the matter—

Resolved, that the Council be recommended to express its approval of the Local Government Bill, 1928, in so far as it attempts to secure unification of the medical services of the country.

The Bill was discussed under three main categories: first, machinery of local administration; second, the effect of the Bill on medical officers of health and poor-law medical officers; and, third, the effect of the finances of the Bill on the health services. He had not put the report before the House in full detail. After endorsing the measure under these several heads in which they were particularly concerned, they proceeded to suggest certain alleviations, modifications, and amendments which could be produced in Committee, and which would be produced in due course. He hoped that members in all parts of the House would combine with him in helping to get amendments accepted in order further to improve the machinery of the Bill. In addition to calling attention to the opinion of the British Medical Association, representing general medical practitioners for the most part, and also working in co-operation with those who were special medical officers of health, he wished to state this, being himself a medical officer of health for a county area in which those matters were constantly to the fore, and who for a period of 12 or 14 years had had to consider and work and report upon the complications which this measure hoped to simplify. In the course of those many years, the county medical officer of health had always, from first to last, felt the hopeless confusion of authority which existed between the different authorities dealing with health, and that, in every way, the work of public health had been crippled because of this very complexity. They had absolute separation between the sanitary authorities and the poor-law authorities. The poor-law authorities dealt with a very large number of questions vital to health, and over these the sanitary authorities of the county council had had no concern and no control. They might have questions of families suffering from tuberculosis which largely came under the poor-law, and it was only when they had gone too far that they came under the sanitary authorities. There was no relation between the poor-law authorities, whether in their relief services or their institutional services, and the sanitary authorities. There was no real combination between the sanitary authorities, on the one hand, and the county authority on the other. The only powers that the county authority had over the sanitary authority was occasionally to report to the Local Government

Board, as it then was, or to the Ministry of Health, as it now was, cases in which the sanitary authority was in default, and it appeared that the Ministry might take certain action. In addition to that, there were, of course, the insurance authorities and other bodies dealing separately with health questions. One of the most crying needs was for some kind of coördination among the different health authorities. The Bill met that in a way that exceeded any proposals that had been made hitherto, and the part that had been alleged against it, that it was a combination of different measures was, from this point of view, clearly in its favour. It was taking the opportunity to bring together an enormous number of these different services, which were required at the same time, in order to get a big move, a big change, and a big reform—indeed, more than a reform, for it was an absolute revolution of local government. Let them consider the position they were in in the counties in regard to fever hospitals. They had fever hospitals started by one of the sanitary authorities, and other hospitals by larger authorities, or combinations of authorities. They had some small authorities left outside existing organisations of sanitary authorities who never knew where to find accommodation for their infectious patients because they were not big enough to start fever hospitals. They had also the small-pox system, with a separate set of hospitals, or with no hospital in the county generally large enough to undertake the provision of proper small-pox accommodation. They had the county council, with no real power to coördinate these cases. This Bill gave the powers, which were laid down, to the council authorities to make definite relations with the sanitary authorities which were running the hospitals, and at the same time to use the institutions of the poor-law for combined purposes. Here they had the possibility of coördinating the whole of the fever hospital services of the county. It was a possibility of enormous advantage in regard to the cause of infection, and one which might lead to economy. At the same time, they might get much more efficient services and more efficient institutions for the patient.

Another point which required coördination, and which had not been mentioned that evening—it was not mentioned by the Minister of Health in his opening speech—was the question of mental hospitals and mental deficiency institutions and the coördination that was required in that respect. A very large amount of work in regard to dementia was the concern of the poor-law and the poor-law institutions, and a large amount of work in regard to the question of mental asylums, mental hospitals, and mental deficiency came under the heading of the county councils. Therefore, they had separate bodies dealing with all these subjects. Under this Bill, they had the possibility of coördinating the work, and by abolishing the poor-law authority the county councils would be able to deal with the mental ailments, dementia, and mental deficiency, as one undivided authority for the whole county area. As a medical officer he could not give unstinted adherence to the Bill without suggesting the necessity for looking into the possibilities and the necessity for amendments.

Maternity and Child Welfare Services.

Suggestions had been made against the Bill from the point of view of those who were concerned with maternity and child welfare services. It was quite true that those were developing services, and were a great essential need of the country. They were services administered very largely by voluntary effort, by women and others who were not ordinarily concerned in battering their way through rules and regulations, and it was certain that a great number of those who were connected with these services were seriously concerned as to the possibilities of danger from the operation of the block grant. They had to look into that. The Minister of Health had said that the last thing he intended to do was to hinder these maternity and child welfare services in any way. He had put into three clauses definite provisions for easing the situation in regard to these services. He (Dr. Fremantle) still hoped that further security would be given than appeared to be given at present. He was not at all sure, although he believed in the block grant system in the long run for the sake of the eventual good to local government, that the time was ripe to apply it at once to the maternity and child welfare services, and it might be advisable and possible to give a little longer time, say, for the first quinquennium, to allow matters to go on under the present system while the voluntary associations were making the adjustments that were necessary to enable them to work the system proposed by the block grants. He hoped that the House would look at the matter in the trust and broadest sense. In the different points of the Bill which affected the public health, with which he had not time to deal, they had to consider not merely the services as they were at the present time, but they had to consider the building up of a stronger, more independent, and more powerful local government system than had existed hitherto. Local government had been weakened because there had been

this enormous diversity and independence of bodies doing this work. In regard to the much debated subject of the local supervising authority under the Midwives Act, a further reservation had to be made in regard to coördination. It was a difficult subject, and obviously it would be better theoretically if the Midwives Acts could be administered by the same authority which administered the maternity and child welfare centres and other Acts. But the difficulty was that midwives and those associated with them felt strongly and knew that the only authority capable of securing the proper experience and the proper inspection of midwives was the county authority. There were minor exceptions, and it was hoped that in regard, at any rate, to that aspect of the midwives' service, the responsibility which was given by this Bill to the Minister of Health to approve or not approve the transfer might be most carefully used. With regard to the proposals to secure unification of the medical services of the country, there were two reservations which should be mentioned, reservations which were capable of adjustment, he hoped, in Committee. The first was with regard to the distribution of poor-law functions. Under Clause 4 it was provided that the poor-law functions might be distributed in regard to health services among the committees of the county councils or county borough councils which dealt already with the Education and Public Health Acts, the Maternity and Child Welfare Act, and so forth. But it used the word "may." That gave them the option of transferring these functions to the new guardians' sub-committees. That would make confusion worse confounded, or rather it would perpetuate the present position, which would be right against the Report of the Poor-law Commission, which this Bill practically proposed to carry out. Members on all sides of the House who had been keen on public health development were even keener on the proper distribution of functions, and the British Medical Association and the medical officers of health were combined in saying that they wanted each committee of the county councils and county borough councils to be responsible for the whole sphere of service, and quite independent of the separate individuals or class of individuals with which they were dealing.

Voluntary Hospital Coöperation.

The question of the hospitals was a most difficult and thorny one. There was naturally a great sensitiveness among all those who were keen upon the voluntary hospitals and all that they meant regarding the competition which might be set up between the voluntary hospitals and the municipal hospitals. The best arrangement for overcoming this difficulty was by means of mutual understanding and coöperation, and it was strongly suggested by the British Medical Association—and he backed the suggestion—that the county and county borough councils should be required to set up hospitals' sub-committees who would be able to advise them regarding the efficient management of the hospitals and effect coöperation with the voluntary hospitals. Some regret might be expressed that the Lunacy Acts were left out of Clause 4. The reason for the omission was that it was intended to deal with the Lunacy Acts in pursuance of the report of the Royal Commission. They had pressed for that for a long time, and he hoped that it would be carried out in the next Parliament. He noted with satisfaction the coördination of the medical officer of health services as a step in the direction of the further increase of whole-time medical officers of health, whether by the coördination of districts or by uniting the services of the county medical officer with those of districts. He was, however, at loggerheads with the Minister of Health in regard to the rural areas. He maintained that they could not say that one system was ideal rather than another, and the suggestion that the only way to deal with rural areas was by whole-time medical officers, who did not engage in private practice, was, in his opinion, wrong. What was wanted in rural areas were men of the best character with the best opportunity to carry out the work. There were obvious exceptions, but there must be some latitude allowed. Those concerned with public health strongly approved the transfer of births and deaths registration to the county authority. With regard to town-planning there was one reservation which he would like to make. He was not at all clear that the financial provisions of the Bill made proper provision for the assistance of those experiments which were largely helped by the Government, such as Welwyn or Letchworth garden cities. Where there were rapidly developing services, there was likely, he thought, to be hardship under the Bill, and he hoped that the matter would be further considered. Lastly, separating the health services from the system of relief. That had been the cardinal policy of the medical profession all along. It was a very difficult question, and he still thought that those who could afford to pay ought to do so, and, on the other hand, they had the precedent of the Infectious Diseases Acts, and he hoped that by degrees, as these municipal health services developed under this new arrange-

ment, the strictly health services might be considered as extra services and separate from relief.

Miss SUSAN LAWRENCE said that the Minister of Health had long wanted this scheme. He projected it in 1925, but it was so unpopular that it had to be dropped. He had introduced a much more unpopular Bill now which was tacked on to the Budget. He would not go down to posterity as a reformer of local government, but as a man who had tried to break up the fabric of local government and who had left the work of repair to others.

Mr. ERNEST EVANS said that the great maternity and child welfare services were new services, and there were still a good many people who required to be more firmly convinced of their value. There was no doubt that the percentage grant had been a great stimulus to expenditure on social services in the past. Under this Bill that stimulus would be checked. The result might be that services of this character would be curtailed in the very districts where their maintenance was essential.

Mr. PETHICK-LAWRENCE said that the great objection of the Labour Party to the Bill was that it would starve the vital services relating to the human needs of the people. It was perfectly plain that local authorities would not be encouraged as they had been to expand their health services.

Viscountess ASTOR said that the Government had brought in a great measure of social reform. There was, however, one rather weak point in it, and she hoped later to move an amendment to take the maternity and child welfare services from the operation of the block grant, and keep them as they were now under the percentage grant.

Superannuation.

Mr. WILLIAM GRAHAM said that no scheme for the improvement of local government was likely to succeed unless they got an efficient, well-remunerated, and contented personnel in the local government service. He therefore urged in the interests of efficiency that the Government should complete the structure of superannuation for local government officers which was permissively built up in 1922. As to the changes which the Government proposed to introduce in the relationship of the National Exchequer to local rates, their scheme left untouched all the percentage grants in education, police, and port sanitary services. The plan of the Government, while ostensibly aimed at the percentage grant, or, on the other hand, at the block grant, really achieved nothing of the kind. He believed an alternative could be found within an improved and more efficient percentage system. There was no validity in the argument that the State did not know and could not determine its own contribution to local services from year to year. Everything that was done by the State in that respect was done in terms of Act of Parliament. There was considerable departmental control, and Treasury and Parliamentary supervision. Efficient return for the State's contribution to local services could be obtained under the percentage system.

Sir BOYD MERRIMAN, Solicitor-General, replying to the points raised in the debate, said that both the amendments of the two Opposition parties did less than justice to the Government's proposals for the administration of the poor-law by the abolition of the guardians and the cooption of those who had experience of the administration of the poor-law. When it was thought that the Government were really going to confine this reform to the substitution of the county councils for the guardians, they were told that they were substituting administration by soulless officials of the county council for the local and personal touch. But now when they looked at the amendments, and the Government's proposals were known, and they had provided for the cooption of those with local knowledge and the personal touch, they were told that they were introducing the vicious practice of non-elected persons, as if they were a new thing in local government. He contended that the formula did take account of the main factors in the present inequality, and that it distributed the money in a proportion which increased as the years went on so as to give effect to the vital necessities. The Government believed that the scheme was going to benefit not only industry but all who were dependent upon industry and all the inhabitants of the country.

The Percentage Grants.

Mr. SIDNEY WEBB said that the Bill did not abolish percentage grants, which at present amounted to between £35,000,000 and £40,000,000 a year. The percentage grants which the Minister wanted to abolish amounted to about £1,000,000 a year, consequently nine-tenths of the percentage grants would still exist. Derating would remain of other grants, but £12,000,000 of that £10,000,000 were block grants already, therefore the Minister was not substituting £10,000,000 of block grants for percentage grants. He was changing the conditions of £12,000,000 of block grants into new block grants, and incidentally and wantonly abolishing £4,000,000 of percentage grants, which were of the highest utility. The abolition of the £1,000,000 of percentage grants would be seriously adverse to the further

development of the optional services. The only provision in the Bill to prevent any backwardation was that which enabled the Minister or the county council to survey the grants, but there was no provision for the Minister's interference at all except in regard to public health. The Minister would not wish to see the progress of maternity and child welfare services stopped in those counties, but it would be stopped because the block grant to the local authorities was coupled with no conditions that they should spend some of it on maternity and child welfare.

With regard to the poor-law proposals, it was very good that Mr. Chamberlain should at last have abolished the statutory ad hoc destitution authorities. The evils of boards of guardians was that they were limited to the relief of destitution; they could not step in before destitution had begun in order to prevent it, and they could not go on a single moment after destitution had ceased in order to prevent a relapse. They were circumscribed in all sorts of ways in what they did. The right hon. gentleman did not sweep that away; he had abolished the boards of guardians, but he had not abolished the poor-law. The local authority was told to recover the cost of maintenance and treatment in institutions. It was provided that the bill to be sent to each patient was the average daily cost per day per patient of the entire institution. Suppose there was a hospital provided for the treatment of a considerable number of patients, and that it happened that there was so little sickness that there was only one patient in the hospital, was the whole cost of the hospital to be charged to that one patient? In any case, the average daily cost per day per patient would be enormous. Take the radium treatment of women for cancer. There might be only eight women under treatment, and in that case the average cost would represent a very large sum indeed. Clause 13 made it obligatory on the local authority to make a charge which included treatment. Surely the threat of being presented with an immense bill would deter poor persons from seeking treatment in these institutions. It had been suggested that this perfectly extortionate charge might be made, but that it would not be pressed. But let the Minister inquire of any medical officer how that would operate. What about the fear of the charge? The Minister wanted these people to come into these institutions before they were destitute; he wanted the poor man suffering from rheumatism to come in before he was broken down and unable to go to work; he wanted the cancer case to come in at the very earliest moment when there was no incapacity, and yet apparently he was going to require the institution to present to every patient a bill of this immense size. He (Mr. Webb) could only imagine that the Minister was paying regard to the susceptibilities of the voluntary hospitals, and that they were afraid that these public health institutions would be so good that people would not want to go to the voluntary hospitals. The Minister had better make haste to agree with his adversary while he might and accept Lady Astor's suggestion to let the maternity and child welfare grants go on.

Parliamentary Secretary's Reply.

After further debate,

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that the Government were well satisfied with the result of the debate. This Bill was certainly the most important contribution to local government reform which had been made in our time. The great vice of the percentage system, especially from the point of view of the health services, was not only that its distribution was flagrantly bad, but that it was haphazard and unscientific. Wigan, for example, received one and a third times the amount that Blackpool got for its health services, but Merthyr Tydvil received not much more than nine-sixteenths of the amount that went to Southport. Surely it was a greater approach towards fairness that under the new formula the gain to Wigan would be six times that of Blackpool, and the gain to Merthyr Tydvil six times that of Southport. He was particularly concerned with the natural anxiety which had been expressed by many good friends of the maternity and child welfare movement. It was an extraordinary thing that under the present percentage system an authority must spend money before it could receive grants. Under the new system it would receive grants in order to be able to spend money. Take the maternity and child welfare services at Gateshead with rates of 23s. 9d. in the £ and 14,000 children, and South Shields with rates of 18s. 2d. in the £ and 13,500 children. They each received an approximate grant under the maternity and child welfare services of £1600, whilst Bournemouth, with rates of 8s. 2d. in the £ and only 5300 children, and Eastbourne, with rates of 9s. 4d. in the £ and only 2976 children, received nearly £2900 and £2700 respectively. That was the result of the present system. Hon. Members would allow that there was an improvement under the new arrangements, and the Government were perfectly open to receive suggestions for their improvement. He wished the House to know that at the present moment the Ministry of

Health were helping the local maternity and child welfare centres to the extent of £178,000 a year more than was done when the Labour Government were in office. If hon. Members would examine Clause 13 they would see that there need be no apprehension that people would be confronted with heavy bills for treatment. As a matter of fact, all they were doing was to follow out the system of the voluntary hospitals of the country.

On a division the Labour Party amendment was negatived by 344 votes to 165—Government majority 179.

The Bill was read a second time.

The Financial Resolution.

On Thursday, Nov. 29th, the House went into Committee on the financial resolution in connexion with the Local Government Bill.

In the course of the discussion, Dr. VERNON DAVIES said that he would like to impress upon the Committee that the figures they were discussing were based upon a hypothetical foundation, and that it was possible when the figures for the "standard" year were brought out they might be very much better or worse than those shown in the White Paper. Various associations had felt it necessary to criticise in some form or other some of the financial provisions of the Bill, but he found that a very important class of local authorities, the urban district councils, had not yet had their case presented to the Committee for consideration, though that case was of great importance. At present the rating resources of the local authority were elastic, inasmuch as they could be expanded when more money was needed, or contracted when less money was needed. The system up to the present had proved ideal from their point of view. They recognised that variations must of necessity take place throughout the country, but each urban district naturally was very anxious that it should not be their particular authority which might have to suffer. Even the population grant was variable; it might increase, remain stationary, or diminish, so that whereas local authorities had now a single elastic system of revenue they would under the Bill have two systems, one elastic and capable of expansion, and the other perhaps non-elastic and capable of no expansion at all. That meant that in the course of time some of these local authorities were bound to lose money. The loss for the first year would be reimbursed, but at the end of the 15 years they would reach the definite position that certain local authorities would be worse off than they were now. It was clear that unless such districts got some help they would be faced with the alternative either of putting an additional burden on the remaining ratepayers, which they might not be able to bear, or of abandoning a necessary or perhaps a vital service which they might have been able to carry out, and would have carried out, if it had not been for the effect of this Bill. The object of the Bill was not to cripple a district, or to restrict its resources, but to maintain them and further to see that they might have increasing resources to meet increasing needs. He hoped that the Government would give some hope or consolation to these urban district councils, and perhaps offer some suggestion which might relieve them of some of their anxiety. The British Social Hygiene Council now got a grant from the State, but under this Bill they would get no such grant. They would be dependent upon grants from the county authorities, but past experience was not very hopeful in this respect, for the county councils and other local authorities had not seemed very anxious to spend money in that direction. If it was possible he hoped that their case might be dealt with because it would be of great benefit to the health services. He was in favour of the block grant for health services. They had reached the stage when people knew the value of the welfare services, and all the authorities who were willing or anxious to avail themselves of those services had done so. Therefore, if they established a system of block grants a larger sum of money would be available, and the result would be that there would be a larger number of welfare centres throughout the country and a good general average of efficiency instead of, as at present, super welfare centres in some places and none at all in others.

Minister's Reply.

Mr. CHAMBERLAIN, replying to points raised in the debate, said that so far from reducing the State assistance to local authorities the Government scheme would increase it from 35 to 45 per cent. of total expenditure. Moreover, if rate-borne expenditure went up the block grant would also go up. The possible increase of the total Exchequer contribution was not limited to £2,000,000 per quinquennium, but might be any figure that Parliament thought it right to fix. The scheme began by giving a larger grant and provided that every fresh need should attract still more at every revision. Mr. SCOTT moved an amendment to the resolution raising the issue that contributions in aid of health services should be by way of percentage grant rather than by block grant. Sir KENNEDY WOOD, in opposing the amendment, suggested that the better course for Members who desired

to raise the question of the percentage system would be to do so at a later stage.

The amendment was negatived by 285 votes to 122—Government majority 163; and the resolution was afterwards carried by 280 votes to 132—Government majority 148.

LOCAL GOVERNMENT (SCOTLAND) BILL.

In the House of Commons on Monday, Dec. 3rd, Sir J. GILMOUR (Secretary of State for Scotland), in moving the second reading of the Local Government (Scotland) Bill, which, in the main, seeks to achieve in Scotland similar objects to those aimed at by the English Bill in England, said that larger units of local government were required, particularly in view of the de-rating proposals. There were glaring inequalities and differences in the burdens which local authorities had to bear. 77 per cent. of the present pauperism in Scotland was in 37 parishes in the larger burghs, and 23 per cent. was scattered over 832 parishes. In the large parishes the cost of administration was about 3 per cent., while in many parishes it was 18 or 20 per cent. of the amount spent in relief. The small authorities were obviously unable of themselves to supply adequate and up-to-date hospital accommodation. The first part of the Bill dealt with local government administration. The services affected by the changes proposed included the poor-law and the major public health services, among which were hospitals and town-planning. It was proposed to set up new authorities as units of administration, consisting of the counties and the burghs of a population of 20,000 and over. The parish councils would be abolished. The administration of poor relief, by far the most important function of the parish councils, was to be transferred to the county. It was proposed that there should be a Statutory Committee dealing with the question of the poor-law within each county to which would be added by co-option persons who were conversant with these problems. For the purposes of the Bill the small burghs were those with a population of under 20,000, and certain of their functions would be transferred to the county councils. Those functions would include the major health services (including infectious disease and maternity and child welfare), milk and dairies, adulteration of food and drugs, unsound food, and town-planning. The total amount of rate loss due to de-rating was estimated in Scotland to amount to £3,200,000 a year. The total cost to the Exchequer in each of the first five years was estimated at £4,125,000. The total extra revenue to local authorities in each of the first five years—new money—was £922,000. The same guarantees were being given to Scotland as in England and the effect broadly of the guarantees would be that in the first quinquennium only three counties out of the 33 would require an additional grant to bring the gain up to 1s. per head to compensate them for the loss of rate and grant. No large burgh would require an additional grant, the amount of the gain in every case being in excess of 1s. per head. The new money being distributed—£922,000—represented a sum of 3s. 9½d. per head of the population, and it was estimated to be equal to a rate of 6½d. in the £ on the reduced rateable valuation of Scotland. Of the smaller burghs 115, or 84 per cent., would have their rates reduced, and of the 869 parishes 585, or 67 per cent., would have their rates reduced. It was calculated that every industrial area would gain and in addition seven out of every eight persons would gain.

An Amendment.

Mr. JOHNSTON moved the following amendment:—
That this House declines to assent to the second reading of a Bill which, by abolishing the existing system of local government, and substituting in its place a system of local government based on foundations of local administration, and perpetuating the inequalities of the present system, is calculated to hinder necessary developments in the public health services; and will add relieving wealthier sections of the community of their proper share of financial responsibility for local government. The Bill, he said, was more drastic, more reckless, more desperate, and deadlier in its attack on local government than the English Bill.

Dr. DUNNED SMITH strongly opposed the Bill, which he said, presented great dangers to the public health services in Scotland. The block grant would adversely affect those services, which were rapidly developing.

Child Welfare.

Referring to the manner in which the child welfare movement had extended, he said that in Edinburgh in 1917, when it was first started, the net expenditure was £35,000. In 1920, before the amalgamation with Leith took place, the expenditure was up to £85,000, and now in the larger area the amount was £115,000 of health expenditure as compared with £35,000 only 11 years ago. This development was also only the beginning of a larger service in view

of the problems facing local authorities to-day. For instance, the question of the rheumatic child had been tackled by the London County Council and also by Birmingham. Another important service was the treatment of crippled children, 75 per cent. of whom could be made self-supporting if they were properly treated in the earlier years. There was the question of mental deficient in regard to which public opinion was now being roused. To give special education to mental deficient up to the age of 16 and then to throw them out without any further public supervision unless in the case of certifiable persons was simply to invite disaster both to them and to the community. There was also the subject of cancer. Something might be discovered at any moment in connexion with cancer, and even just now it was being realised that supplies of radium, which were very expensive, were essential in the treatment of that problem. Child welfare and maternity work was ripe for a very big advance and public opinion was ripe for that advance. They had been hearing a great deal of talk about maternal mortality. Dr. Findlay, the child welfare officer of Edinburgh, had pointed out that in 1927 in Edinburgh the figures of the maternal death-rate among mothers who had no antenatal attention were 11.2 per 1000 confinements, while in the antenatal clinics it was only 2.4. The total figures were not large enough for the actual scientific determination of these proportions, but it was plain that as Dr. Findlay said, they must conclude that the antenatal clinics very definitely assisted in lessening the maternal death-rate. There was not enough of this work to cover the field either in Edinburgh or elsewhere in this standard year. This year was the standard year, and it was going to determine the relative proportion of money to be given in the grants for the next five years. Therefore if the extension of this service was proposed in Edinburgh and other places—there were already schemes for homes and for other things to deal with these cases—the person responsible for the finances would say, "No, we cannot go on with that now. We have got our grant on the basis of this year's expenditure. We must wait until the fourth year, until the next standard." He did not think that that was a satisfactory position for the health services, and it seemed to him that the 64d. which the right hon. gentleman told the House was going to be saved in rates, or given as a present by this Bill, would very soon be wiped out by the inevitable increases in expenditure, which would result from the normal development after this year, and which would have to be met on a very narrow rating basis and would certainly cause an increase in the rate.

Veneral Disease.

The same thing applied in regard to venereal disease. At the present time the State paid 75 per cent. and the local authority paid 25 per cent. Now the local authority was to pay the whole 100 per cent., and while it was likely that large cities like Edinburgh would maintain their service, there would be no stimulus to those backward areas which had never provided any efficient V.D. service to pass the standard year and to go forward and impose on their own ratepayers the charge for the necessary extension of those services. The Government had taken up a very strong line in regard to what the Edinburgh authorities put forward for compulsory treatment in venereal disease. They had turned that down. At the same time in this Bill they had cut out the grant for propaganda. If the voluntary system was to be successful in venereal disease, propaganda was absolutely essential and propaganda must be national, because voluntary contributions had been tried before and had been entirely unsuccessful. Such things as films and various items could not be supplied by individual authorities but must be done nationally. This had all been cut out by this Bill. Some people had said that they looked forward to this Bill as a great help for public health. He wished he could think so. He thought that it was a backward measure and that it was going to be a terrible danger to public health. It was not going to be maintained, and if it was it would only be by the sacrifice of local authorities in rating their own people rather than let the services suffer.

Scottish Hospitals.

There was one last word with regard to hospitals. He would like to have information about that, because the point had never been cleared up. Under this Bill the town councils were going to take over institutions such as the large hospitals in the cities which at present were run by the parish councils. They had two hospitals in Edinburgh—Craiglochart and Craigleith. It was proposed that all the poor people would be taken from Craiglochart and kept in Craigleith which had been restored to them after the war pensioners had used it. He thought Craiglochart ought to be used as an overflow for the Edinburgh Royal Infirmary, which had a waiting-list of over 2000 with many urgent cases wanting to get in. What was to be the position? Was it the case that Edinburgh Town Council would only be able to treat in that hospital necessitous poor, and would

Edinburgh be compelled to get back from the relatives of these people so treated any sum expended on their maintenance? In Aberdeen at the present time there was a working arrangement and the parish council hospitals had been handed over to the public health committee of the town council and were being worked by them. In Glasgow there was a working arrangement with Stobhill, one of the best fitted-up hospitals in the country. What was going to be the new position? Did the new proposals compel the town council to treat the people in those hospitals, if they were intending to use them as general hospitals, differently from the people in the tuberculosis hospitals? That was a very important point, which he would like to see cleared up. Another point which was of some importance was that one of the advantages of the new proposal was that these new institutions which were taken over were going to be brought up to date. We know that many of the poor-law institutions were out of date and badly equipped. Who was going to pay for bringing them up to the proper standard of equipment? He hoped that no considerations of any kind would prevent every facility being given and every accommodation being taken advantage of for the medical services of people who required it. He thought there would be opposition from those people who believed that a well-equipped and well-run municipal hospital would tend to damage the voluntary hospitals of the district. He believed, however, that for many years there would be plenty of room for both of them, and he hoped that the municipal authorities would be encouraged to use those institutions to the utmost capacity. He would like also to know what was going to happen to the Highlands and Islands Medical Fund.

Reply on the Debate.

The debate was resumed on Tuesday, Dec. 4th.

Major ELLIOT (Under Secretary of State for Scotland), replying to points raised in the debate, quoted from reports and speeches delivered by prominent Members of the two Opposition parties in support of local government reform, the abolition of parish councils, and the transfer of their functions to the town councils and county councils. He contended that the scheme had been very fully discussed in Scotland, especially by the municipality of Glasgow which contained a large number of Socialist members, and there was no suggestion of party opposition to the measure on the part of the Socialist members of the Glasgow Corporation. He hoped, therefore, that they had heard the last of the accusations that the scheme had been brought forward without any previous consideration or discussion, and that its proposals were of an undemocratic and bureaucratic character. Proposals were included in the Bill to secure that there should be working-class representation on the new bodies to be set up. The Bill was not a backward step, but a step forward in that respect. Committee after committee had reported in favour of the movement of the health services from the education authority to a single health authority. The Bill would put the five great semi-national services of Scotland—the roads, public health, education, poor-law, and police services—on the widest possible bases.

The amendment was rejected by 319 votes to 150, and the Bill was read a second time.

SITUATION IN DISTRESSED AREAS.

In the House of Commons on Monday, Dec. 3rd, Mr. CHAMBERLAIN, replying to requests by Mr. LANSBURY and Mr. MORGAN-JONES that the Government should take action to deal with the position in the distressed areas, said that a fortnight ago he sent his chief inspector to South Wales, accompanied by a competent medical man, to make a thorough investigation on the spot and to go into the homes of the people. The inspector was being assisted by people on the spot who had taken a special interest in the matter. He (Mr. Chamberlain) hoped before long to receive a report which would show him more accurately than anything he had hitherto been able to get of the situation in that area. When he got that report he would take very serious thought as to what might arise out of it.

HOUSE OF LORDS.

TUESDAY, DEC. 4TH.

Voluntary Boarders in Public Asylums.

Lord SANDHURST asked if the Government would in the present session introduce legislation to enable voluntary boarders to be received into public asylums.

The Earl of CRANBROOK urged that legislation should be introduced, both on the grounds of economy as well as of humanity. He said that it would also be in the interests of the medical profession. Doctors would be able to study these cases in their early stages, and the treatment of mental disorder would be able to be linked up with general practice in a way which was not possible at present.

The Earl of ONSLOW said that there were difficulties in dealing with the recommendations of the Royal Commission on Lunacy separately, and the Government hoped to deal with them as a whole. It was impossible to introduce a comprehensive Bill this session, but the Government hoped to deal with the whole subject of lunacy and mental disorder as soon as possible. He assured their lordships that provision for the admission of voluntary boarders into public asylums would find a place in the proposed measure.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 28TH.

London Poor-law Hospitals.

Lieut.-Colonel FREMANTLE asked the Minister of Health (1) what was the number of beds actually available in each poor-law hospital in London for the sick in wards staffed by trained nurses; (2) what was the actual number of beds in infirm wards served by untrained attendants in the poor-law institutions in London; (3) what was the number of trained nurses and untrained attendants, respectively, in the poor-law hospitals and infirm wards of the poor-law institutions in London.—Sir KINGSLEY WOOD replied: Wards for the sick and infirm in the separate infirmaries of London which are ordinarily staffed by trained nurses, probationers in various stages of training, and ward maids or attendants, contain 16,520 beds. Wards for the sick and infirm included in other poor-law institutions are usually staffed by trained nurses, assistant nurses, and attendants, and contain some thousands of beds. My right hon. friend regrets that no more precise figures for the number of beds or the number of nurses and attendants are available.

Milk Provision for Maternity and Child Welfare.

Viscountess ASTON asked the Minister of Health if he would, at a proper time and early date, withdraw the cut which he made in the moneys granted for milk provision for the maternity and child-welfare services.—Sir KINGSLEY WOOD replied: I assume that my hon. friend is referring to the reduction of about £12,000 which was made in the grants available for certain local authorities in aid of their expenditure on milk during the present financial year. This reduction, which was purely temporary, had to be made in order to keep the grants paid by my department for the health services within the amount voted by Parliament. I may add that similar action will not require to be taken during the next financial year.

Sexual Offences Against Young Persons.

Viscountess ASTON asked the Home Secretary what steps had been taken to carry out the recommendations of the Departmental Committee on Sexual Offences against Young Persons, which reported in December, 1925, and also those of the Departmental Committee on the Treatment of Young Offenders, which reported in March, 1927, other than those covered by the Home Office circulars issued on Sept. 30th, 1927, and July 20th, 1928.—Sir W. JOYNSON-HICKS replied: It would be impracticable in the course of an answer to a Parliamentary question to refer in detail to the various matters dealt with by the two committees, which, as my noble friend is aware, covered a very wide field. A new report of the Children's Branch will be issued in the course of a few days, and this will give some account of the progress made. The two circulars mentioned dealt fully with many aspects of the subject of young offenders, including the important questions of the organisation of juvenile courts and the use of hostels and houses in connexion with the probation system as an alternative to imprisonment, and showed how much could be done by the justices under their existing powers. I understand that in many places the justices have carefully considered these circulars, and have arranged to modify their practice in accordance with the recommendations. A circular was issued to justices on Sept. 17th, 1929, as regards the recommendations of the Sexual Offences Committee, and I am considering, with the aid of the best advice I can obtain, whether it would be right at a suitable opportunity to propose changes either in law or in the practice of the Higher Courts in some of the many directions indicated by the Committee. As to those recommendations which cannot be carried out without legislation, the Government is most anxious to introduce a Bill to amend the Children Act as soon as Parliamentary time can be found.

THURSDAY, NOV. 29TH.

Glassworkers' Cataract.

Mr. WARDLAW-MILNE asked the Home Secretary whether his attention had been called to cases of glassworkers' cataract resulting in total disablement; and, if so, whether he would consider extending the provisions of the Workmen's Compensation Act Order (S. R. and O. 1918, No. 287), as amended by S. R. and O. 1923, No. 6, so as to put glassworkers in

the same position as regards compensation as workers in iron and steel manufactures.—Sir WILLIAM JOYNSON-HICKS replied: I have recently had under consideration the desirability of amending the existing provisions as to glassworkers' cataract on the lines indicated in the question, and have asked the Glass Manufacturers' Federation if they desire to offer any observations. I will inform my honourable friend of the result in due course.

Importation of Indian Opium.

Mr. WELLOCK asked the Home Secretary whether it was now the policy of the Home Office to import opium from India in the form of manufactured alkaloids; whether such alkaloids were instead of, or were in addition to, the medical opium habitually imported from India; and whether he could give an assurance that there had not been and would not be an increase in the amount of opium imported, whether as medical opium or as alkaloids.—Sir WILLIAM JOYNSON-HICKS replied: During the past four years both raw opium and crude morphine have been imported into this country from India for the purpose of manufacturing drugs. They have taken the place to a considerable extent of opium imported from other countries. It is not possible for me to give such an assurance as is asked for in the last part of the question, as the amount of opium required for medical and scientific purposes, whether for use in this country or for export, necessarily fluctuates to some extent from year to year, but the honourable Member may rest assured that the trade is very carefully supervised and, in fact, there has been a progressive decrease in the amounts imported in recent years.

Block Grant and Maternity and Child Welfare.

Viscount SANDON asked the Minister of Health what was the gross amount and the average amount per local authority which would be gained to them annually under the head of maternity and child welfare services by the operation of the block grant as opposed to the percentage grant.—Mr. CHAMBERLAIN replied: The gain in grant of counties and county boroughs under the scheme will be general, and no specific part can be said to arise under the head of the maternity and child welfare service. As regards maternity and child welfare authorities other than counties and county boroughs, the addition to the general Exchequer grant of the authorities for the purpose of the maternity and child welfare services will be determined by a scheme to be made by the Minister according to the services to be carried out and the circumstances of the areas.

Public Instruction on Food Values.

Mr. BEXTON asked the Minister of Health whether he was aware of the public demand for information as to the purity of certain preserved foods; and whether he would issue statements giving guidance on the question of the comparative hygienic value of chilled or frozen meat and fresh meat and tinned and fresh fruit, respectively.—Mr. CHAMBERLAIN replied: I am glad to observe a growing public interest in the purity of food, and I will consider whether there is any information in regard to the points mentioned by the right hon. gentleman which it would be of advantage to publish.

FRIDAY, NOV. 30TH.

The Schick Test in London Boroughs.

Mr. DAY asked the Minister of Health which of the metropolitan borough councils had undertaken, with the sanction of his department, immunisation work by means of the Schick test for the purpose of reducing the attack-rate of diphtheria.—Mr. CHAMBERLAIN replied: The following metropolitan borough councils have, with the sanction of my department, undertaken immunisation work of the kind referred to: Battersea, Camberwell, Deptford, Finsbury, Holborn, Lambeth, Poplar, St. Margerybone, Stoke Newington, Wandsworth, and Westminster.

MONDAY, DEC. 3RD.

Nourishment for Children in Necessitous Areas.

Sir ROBERT THOMAS asked the President of the Board of Education how far local education authorities provided meals, milk, cod-liver oil, and malt extract, or other nourishment to children in the necessitous areas who were suffering from malnutrition and whose parents were not in a position to provide them with sufficient food: what authorities, if providing for the children; and, if the powers of the education authority clashed with those of the poor-law the two bodies.—The Duchess of ATHOLL (Parliamentary Secretary to the Board of Education) replied: At the present time approximately 120 local education authorities are providing meals or other nourishment for necessitous children. The authorities in the Welsh coalfields who

undertaking such provision are Monmouth, Glamorgan, Cardiff, Merthyr, Newport, Swansea, Aberdare, Abertillery, Barry, Pontypridd, and Rhondda. Arrangements have been made for securing close coöperation between the education and the poor-law authorities.

Non-destitute Persons and Hospital Treatment.

Viscount SANDON asked the Minister of Health whether local authorities would have power, except in cases of infectious disease, to recover from the non-destitute expenses for treatment in their hospitals as well as for maintenance, to which he stated it was limited, in view of the terms of the last two lines of Subsection (3) of Section 13 of the Local Government Bill.—Sir KINGSLEY WOOD replied: Yes, Sir, to the extent of the average daily expenditure of the hospital on treatment, but not by reference to the actual cost of the treatment of the particular patient.

TUESDAY, DEC. 4TH.

Maternity and Child Welfare in Scotland.

Mr. ERNEST BROWN asked the Secretary of State for Scotland the total number of local authorities in Scotland empowered to make provision for maternity and child welfare; and the number of such authorities that made such provision in 1927-28 or to the latest available date.—Sir J. GILMOUR replied: There are 307 public health local authorities in Scotland, all of whom have powers under Subsection (1) (b) of Section 3 of the Notification of Births (Extension) Act, 1915, subject to the approval of the Scottish Board of Health, to make arrangements for attending to the health of expectant and nursing mothers and of children under 5 years of age. The number that have made such provision up to date is 243.

Births, Marriages, and Deaths.

BIRTHS.

- RODD.—On Nov. 25th, at Yelverton, Devon, the wife of Captain Arthur Rodd, late R.A.M.C., of a daughter.
SHERIDAN.—On Nov. 28th, at Parkfield House, Didsbury, Lancs., the wife of Major B. C. O. Sheridan, M.C., R.A.M.C., of a daughter.
WAY.—On Dec. 4th, at 923, Finchley-road, N.W. 11, to Phillis (*née* Pelissier), wife of Dr. C. Berkeley Way, M.C.—a daughter.

DEATHS.

- CLARK.—On Nov. 30th, at College-gardens, Dulwich, John Thomson Clark, M.B., Ch.B., D.P.H., aged 56.
HORT.—On Nov. 27th, 1928, at Saigon, French Indo-China, Violet Gordon Hort, eldest daughter of the late Edward Collett Hort, F.R.C.P. Ed., formerly of 8, Harley-street, W., and of Mrs. Hort, of Scaford, Sussex.
KERR.—On Nov. 26th, at 1, Claremont-place, Sheffield, William Smith Kerr, M.B., C.M., F.R.C.S. Ed.
MACGREGOR.—On Nov. 27th, at Orchard Bank, South Promenade, Lytham St. Anne, after a long illness, John MacGregor, M.D., L.R.C.P. & S. Edin., M.R.C.S. Eng.
NESBITT.—On Dec. 1st, suddenly, at Hilgay, Norfolk, James Nesbitt, L.R.C.P., L.R.C.S. Edin., aged 68.
STEWART.—On Dec. 2nd, at Burleigh-mansions, Charing Cross-road, W.C., James Stewart, F.R.C.P. Edin., L.R.C.S.I., L.M. Dub.
N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SNAKES OF CENTRAL AMERICA.—The United Fruit Company is coöperating vigorously in the development of antivenines throughout Central America. Section V. of the sixteenth annual report, to which we have already referred, is devoted to snakes and snake-bite. There is a curious scarcity of trustworthy data concerning the snakes of this region and the effects of their bites. Hence, at Tela, Honduras, a serpentarium has been organised, and here Dr. T. Barbour has reported on 3349 specimens, a collection which contained 31 species of harmless snakes (2746) and four species of poisonous snakes (603 specimens), and of these 352 were the dreaded *fer-de-lance* (*Bothrops atrox*). The capture of these thousands of snakes did not result in a single case of snake-bite, yet during this period ten cases of snake-bite were admitted to Tela Hospital, only two of which were serious enough to require antivenine treatment. Enough venom has now been collected and shipped to start the manufacture and distribution of *fer-de-lance* serum, and some information concerning the breeding habits of this species has been obtained. Its fecundity is remarkable. Photographs are shown of a female snake which produced a litter of 72 live young weighing in the aggregate 1.66 lb. The young *fers-de-lance* are active and venomous within 24 hours of birth when their average length is 13 inches and weight 10.5 g.

Obituary.

MICHAEL MARTIN DAVITT, M.B., B.Sc. N.U.I.

THE death of Dr. Michael Davitt occurred at Galway on Dec. 1st after a very short illness. Thirty-eight years of age, he was the eldest son of the late Michael Davitt, a well-known public man in Ireland and for a time a Member of Parliament. He was educated at University College, Dublin, taking the degree of Bachelor of Science in the National University of Ireland in 1911 and the degree of Bachelor of Medicine in 1914. In 1917 he was appointed visiting physician to Jervis-street Hospital, Dublin, but in 1919 relinquished this appointment and engaged in practice in Wales for some years. In 1922 he was appointed physician to the newly established Central Hospital in Galway, and soon afterwards became lecturer in clinical medicine at University College, Galway. Speedily gaining a reputation as a sound physician, he had for some years past enjoyed a growing consulting practice. He took an active part in public affairs, both local and national, and was nominated a candidate for the Senate for the election which was held this week, his return being considered certain. On Nov. 30th he felt unwell and complained of stiffness in the neck. The condition soon declared itself as tetanus, and he succumbed on the afternoon of the following day. It is stated that he had had a previous attack of tetanus two years ago. Dr. Davitt was a man of much ability and public spirit to whom a bright and useful future seemed assured.

MONTY BARANOV, M.D. LOND., D.O.M.S.

WE regret to announce the death at Johannesburg of Dr. M. Baranov, by which a promising career in ophthalmic surgery has been cut short. Born at Vryheid, Natal, in 1895, he was educated at King Edward VII. School, Johannesburg, matriculating in 1912 when he went on to University College, London, for his medical studies. He became a prosector in anatomy at the Royal College of Surgeons, took the Conjoint qualification in 1918, and acted as house physician to Dr. Bolton at University College Hospital. He graduated M.B., B.S. Lond. before going to France with a commission in the R.A.M.C. On his return he took the M.D. in general medicine while casualty officer at his hospital, and assisted Mr. Percy Flemming and Sir John Parsons with a view to proficiency in ophthalmology. He then entered Moorfields and rose to the position of senior house surgeon and chief clinical assistant, taking the Conjoint diploma in ophthalmology. Towards the end of 1923 he returned to South Africa, and in the following year was elected honorary assistant ophthalmic surgeon to the Johannesburg General Hospital, where he was actively at work until some six weeks before his death. He took a keen interest in his non-European work in which his fine operative ability soon made itself manifest.

Dr. Baranov possessed social gifts of a high order. On the testimony of one of his old teachers we learn that he was highly popular with the medical and nursing staff at Moorfields, and his popularity followed him to South Africa, where his qualities secured for him the confidence and affection of his colleagues. He was full of the joy of life in work and spent himself in care for his patients.

In December, 1926, Dr. Baranov married Miss Clara Rosenberg, of Johannesburg, and much sympathy is felt for his young widow.

Mr. E. C. Harries, headmaster of West Buckland School, Barnstaple, writes that Dr. William Hill was educated at this school and was a prominent member of the Old Boys Club.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Dr. A. F. R. Wollaston has been re-elected to a Fellowship at King's College, and has been appointed tutor.

UNIVERSITY OF LONDON.—The Diploma in Psychological Medicine (with special knowledge of psychiatry) has been conferred, after examination, on Dr. Kathleen A. H. Sykes.

The Paul Philip Reitlinger Prize, offered this year for the best essay embodying the result of some research work on a medical subject carried out by the candidate, has been awarded to Geoffrey William Rake, M.R.C.S. Eng., a student of Guy's Hospital Medical School, for an essay on Achalasia of the Cardia. The prize, of the value of £30, was founded by Mr. Albert Reitlinger in memory of his son, a student of Middlesex Hospital Medical School, who died in 1911.

UNIVERSITY OF DUBLIN.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O.

Medicine.—*Arthur Geoffrey Thompson, *William John Edward Jessop, *Nora Adrienne Stack, Gerald Cecil Dockeray, Dermot Francis Walsh, Mollie Finegan, John Edward Cooper Cherry, John Ernest McMahon, John Terence McGinn, Ion Wellesley Pigott, Eric Francis Sanderson Morrison, and Charles Murrough O'Brien.

Surgery.—*Arthur Geoffrey Thompson, *Gerald Cecil Dockeray, Dermot Francis Walsh, William Rothschild Johnston, John Ernest McMahon, *Ernest du Plessis Meiring, *Nathan Shapira, Robert Ian Gillespie Reid, John Beggs, *Frederick Richard Falkiner, *Isaac Fisher Ratthaus, *Julius Horwich, *Cecil King, and *Frederic Severne Mackenna.

Midwifery.—*Lionel Brent Harris, *Thomas Brown McMahon, Geoffrey Berry Thrift, Charles Morrison Taylor, Rex St. John Lyburn, William Bruce Hamilton, Charles Murrough O'Brien, Robert Ivan Reid, Allyn Henry O'Malley, Edward Bethel Andrade Solomons, Norman Sydney Klass, George Kenneth Graham, John Beggs, *Alan Francis Kennedy, *Patrick Alban Thornton, Frederic Severne Mackenna, and William Ivan Chapman.

FINAL EXAMINATION FOR B.DENT.Sc.

Francis Bertram Sumerling and Michael Emanuel Mofsovitze.
*Passed on High Marks.

HOSPITAL SATURDAY.—The amount collected on Hospital Saturday, Oct. 6th, in London, was £2039.

OXFORD OPHTHALMOLOGICAL CONGRESS.—The following have been elected to hold office in 1929:—Master: Bernard Cridland. Deputy Master: Philip H. Adams. Hon. Treasurer: Robert J. Coulter. Hon. Secretary: C. G. Rusa Wood, to whom communications should be addressed at 12, St. John's Hill, Shrewsbury. The next meeting will be held from July 14th to 6th, 1929.

ROYAL INSTITUTION.—A general meeting of the members of the Royal Institution was held on Dec. 3rd, Sir Arthur Keith, treasurer and vice-president, in the chair. Miss Edith Aird, Sir John Aspinall, Sir John Beale, Dr. R. T. Beatty, Miss K. Hartree, Viscount Hambleden, Mr. E. Hantschek, Mr. B. Hennell, Mr. C. W. G. Hindley, Mr. J. S. Oliver, Mr. R. Pigott, Miss L. Power, Mrs. E. A. Ronald, and Mr. C. Swithinbank were elected members.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.—At the annual meeting of the Court of Governors of the School, which was held on Nov. 30th in the Council Room of the B.M.A. House, Tavistock-square, Sir Holburt Waring being in the chair, substantial progress was reported in the organisation of the School and in the new building. The Director reported an increase of no less than 17 per cent. in the proportion of success among students sitting for the diploma in tropical medicine and hygiene. Advanced courses in bacteriology have been established in temporary quarters in Gordon-square, and all of the five students who entered for the new diploma of London University obtained it. Special courses in epidemiology and vital statistics have also been established. The professors of public health, of biochemistry, and of chemistry as applied to hygiene, who have already been appointed, will enter upon their duties next summer, when it is hoped that the handsome building in Portland-stone which is being completed in Bloomsbury to the design of Mr. Morley Horder and Mr. Vernon O. Rees will be opened.

Dr. H. R. Newham, C.M.G., the Warden of Studies, has been appointed also curator to the museum; and Dr. J. P. C. Hedham, director of library services, and Mr. R. L. Sheppard, assistant director of library services. Mr. C. C. Bernard will retain his post of librarian in the new organisation.

CROSLAND MOOR POOR-LAW INSTITUTION.—Sir Berkeley Moynihan last week opened a new block of this institution belonging to the Huddersfield Board of Guardians. Four large wards and two smaller ones will accommodate 109 patients; the cost has been approximately £183 per bed.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A meeting will be held at the Society's House, 17, Bloomsbury-square, London, W.C., on Tuesday, Dec. 11th, at 8 P.M., when Miss Katharine Coward, D.Sc., will give an address on Recent Research on the Vitamins, illustrated by lantern slides. Medical friends of members and student-associates will be welcomed.

RATES ON HOSPITALS.—The assessment of Finchley Memorial Hospital has been increased by 500 per cent. It is officially stated that since the enlarged assessment was the work of the Panel of Valuers the Valuation Committee felt obliged to accept it, but would fully support an appeal.—Alderman Kingston, deputy mayor of Brighton, where there have also been heavy increases in hospital assessments, last week suggested that the difference should be given back by the corporation. The assessment of the Sussex County Hospital has been raised from £100 to £1600.

BRITISH HONOUR FOR EGYPTIAN SURGEON.—At the Medical Congress to be held this month in Cairo, Sir Berkeley Moynihan, President of the Royal College of Surgeons of England, will admit Ali Bey Ibrahim, Professor of Surgery of the Faculty of Medicine of Cairo University, to the honorary fellowship of the College.

LORD BIRKENHEAD'S PENSION FOR HOSPITALS.—Lord Birkenhead announces that his pension of £5000 a year as an ex-Lord Chancellor is, less income-tax, to be placed in the hands of trustees "in favour of certain approved and contingently selected hospitals."

PAYING PATIENTS AT GLASGOW.—A new wing is to be added, at a cost of £25,000, to the Victoria Infirmary, Glasgow, for the reception of paying patients. It will accommodate about 30 patients who will pay an inclusive fee of £6 6s. per week for the first three weeks, and £3 3s. per week thereafter.

MOTORISTS AND HOSPITALS.—The Royal Victoria Infirmary, Newcastle-on-Tyne, has received a cheque for £500 subscribed by 4000 motorists which has been added to the motor section of the Infirmary Appeal Fund. It is officially stated that there is a ward constantly full with motor accident cases, and that the cost of treating them is about £5000 a year.

ILLEGAL USE OF FORMALIN TO PRESERVE MEAT.—A butcher and his assistant were recently fined rather heavily at Mortlake for treating meat with formalin. The summonses were in respect of shin of beef, stewing steak, and scrag of mutton, showing that the defendants used the preservative in a rather wholesale way. Mr. E. Hinks, public analyst for Surrey, testified to the presence of formaldehyde in all three samples, a fact that was not disputed by the defendants who pleaded guilty. They did not know, they said, that formalin was harmful; they had used it to prevent the meat "going clammy" over the week-end. The prosecuting solicitor opined, in answer to a question from the bench, that there was not a butcher in the kingdom who did not know that formalin must not be used in that way. This is the first prosecution of the kind in Surrey, and it raises the question to what extent this practice is followed by butchers. We know that the official organisations of the trade disapprove of the use of preservatives, but it is not unlikely that individual traders find that wiping over or spraying with formalin gives meat a fresh appearance and so use it. Medical officers and public analysts in other places than Mortlake would do well to make investigations to see whether this very objectionable practice goes on in their districts. It is possible that the majority of people could eat meat treated with formalin for years, as indeed one of the defendants said he had done, without any obvious ill-effects, but there are many who without being exactly invalids are not well equipped physically for incurring the risks of malnutrition and indigestion which "doped" foods necessarily present. Besides this, practices of the kind under consideration greatly complicate all questions of diagnosis and diet in ailments of the digestive organs.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Dec. 10th.—5 P.M., WAR. Paper: Surgeon-Commander P. M. Rivaz, R.N.: Some Common Problems in Naval Hygiene.

TUESDAY.—5.30 P.M., THERAPEUTICS. Paper: Prof. E. B. Verney: The Purines as Diuretics. A discussion will follow. 8.30 P.M., PSYCHIATRY. Paper: Dr. W. A. Potts: Delinquency.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Tercentenary of Malpighi. Paper: Prof. Franchini (Bologna): Malpighi. Members are invited to bring objects (books, prints, documents, instruments, medals, &c.) of historical interest for exhibition at the meetings of this Section.

THURSDAY.—8.30 P.M., NEUROLOGY. Short Papers: Dr. Parkes Weber: A Note on the Association of Extensive Hæmangiomas of Nævus of Skin, with Cerebral (especially Meningeal) Hæmangiomas. Dr. J. G. Greenfield: Measles Encephalitis. Dr. R. M. Stewart: The Pseudo-polyneuritic Type of Amyotrophic Lateral Sclerosis.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Cases: Dr. C. Worster-Drought: A Case of Bullet in Brain for 13 Years. Dr. F. G. Chandler: A Case of Oleothorax. Mr. W. E. Tanner: Bilateral Central Osteomyelitis of Humeri Following Puerperal Sepsis. Dr. B. S. Nissé: A Case of Congenital Heart Disease with Arborisation Block. Dr. Bernard Myers and Mr. St. J. D. Buxton: A Case of Severe Rickets. Dr. J. D. Rolleston: Cases of Tracheotomy for Laryngeal Diphtheria in Mother (1896) and Daughter (1928). Dr. F. Parkes Weber: Post-mortem Specimen from Case of Stenosis of the Aortic Isthmus shown before the Section on Oct. 12th, 1928. Other cases will be shown. 5 P.M., OPHTHALMOLOGY. Clinical Meeting, at the Royal Westminster Ophthalmic Hospital, Broad-street, Holborn, W.C. (nearest tube stations—British Museum and Tottenham Court-road). Tea at 4.30 P.M. 8.30 P.M., ELECTRO-THERAPEUTICS. Paper: Dr. C. A. Robinson: The Treatment of Pelvic Inflammation by Diathermy.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Dec. 10th.—8.30 P.M., Discussion on Sacro-iliac Pain, to be introduced by Dr. Wilfred Harris, Mr. P. J. Verrall, and Dr. James Brailsford.

BIOCHEMICAL SOCIETY.

FRIDAY, Dec. 14th.—5 P.M. (in the Laboratories of J. Lyons and Co., following C. Drummond and the Vitamin... B. Russell Wells and P. Haas: The Hydrolysis of Carrageen Mucilage. C. R. Harington: The Resolution of Di-thyroxine. M. W. Goldblatt: The Action of Insulin in Young Rabbits. E. Clenshaw and I. Smedley Maclean: The Nature of the Unsaponifiable Matter from the Lipoids of Spinach and Cabbage Leaves. L. H. Lampitt and P. Bilham: The Effect of Some Constituents of Milk on its Hydrogen-ion Concentration. D. H. F. Clayson: The Diastatic Digestion of Raw Wheat Starch. L. H. Lampitt and J. B. Bushill: Some Observations on the Determination of Surface Tension (by the Ring Method) with Special Reference to Egg Albumin. E. B. Hughes: Some Observations on the Production of Liesegang Rings. J. Pryde and E. T. Waters: The Nature of the Sugar Residue in the Hexosemonophosphoric Acid of Muscle. O. Rosenheim and T. A. Webster: The Biological Inertness of Irradiated Mycosterols other than Ergosterol. O. Rosenheim: A Specific Colour Reaction for Ergosterol.

ROYAL SOCIETY OF TROPICAL MEDICINE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Dec. 13th.—8.15 P.M., Dr. A. Knvett Gordon: The Role of the Spleen in the Causation of Hæmorrhage. Preceded at 7.45 P.M. by a demonstration.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

WEDNESDAY, Dec. 12th.—8 P.M., G. G. Blake, M.I.E.E.: Application of Electricity to Medical Practice.

HARVELAN SOCIETY.

THURSDAY, Dec. 13th.—8.30 P.M. (at the Paddington Town Hall, Harrow-road), Mr. A. E. Giles: Sterility and its Treatment. There will be a discussion after the paper.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Dec. 10th.—10 A.M., Dr. Dowling: Skin Department. 11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases (demonstration). 2 P.M., Dr. Shaw: Medical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose and Ear Department.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Department.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Department.

SATURDAY.—9 A.M., Mr. Vlasto: Operation on Throat, Nose and Ear. 9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily 10 A.M. to 5 P.M., Saturdays 10 A.M. to 12 noon. Medical and Surgical In-patients and Out-patients. Operations, Special Departments, Anæsthetic Course.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 10th.—2.30 to 5 P.M.: Medical, Surgical, and Gynaecological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 11th.—5 P.M., Dr. S. E. Dore: Erythematous squamous Eruptions.

THURSDAY.—5 P.M., Dr. W. N. Goldsmith: Pigmentation of the Skin.

LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Dec. 14th.—4 P.M., Mr. Nicol Rankin: Earache.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Dec. 12th.—4 P.M., Prof. E. W. Hope: Industrial Diseases as Viewed from the Standpoint of a Medical Officer of Health.

NATIONAL INSTITUTE FOR THE DEAF.

TUESDAY, Dec. 11th.—8 P.M. (at Eustace Miles Restaurant, 40, Chandos-street, W.), Mr. C. M. R. Balbi, A.M.I.E.E.: Facts on Deafness. Silver collection.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Dec. 11th.—4.15 P.M., Dr. J. Wharton: Demonstration of Ophthalmological Cases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Dec. 14th.—3.30 P.M., Dr. Wilkie: X Rays in the Diagnosis of Gastro-Intestinal Lesions.

Appointments.

YELLOWLEES, H., M.D. Glasz., F.R.F.P.S. Glasz., F.R.C.P. Edin., has been appointed Physician for Mental Diseases to St. Thomas's Hospital.

Certifying Surgeons under the Factory and Workshop Acts: ELKINGTON, G.W., M.B., B.S. Lond. (Bruton, Somerset); PHILIP, P. W., M.B., Ch.B. Aberd. (Huntly, Aberdeen); PHILLIPS, D. B., L.R.C.P. Lond., M.R.C.S. (Loughor, Glamorgan); and SELBY, H. J., L.R.C.P. Lond., M.R.C.S. (Newnham, Gloucester).

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road, N.W.—Sen. and Jun. H.S.'s. At rate of £200, £150, and £100 respectively.

Bihar, India, Jharia Mining Settlement.—Chief M.O. 1200 Rs. a month.

Birmingham, Ear and Throat Hospital.—Second H.S. At rate of £150.

Birmingham, Queen's Hospital.—Asst. Ophth. Surgeon. £50.

Birmingham, St. Chad's Hospital.—Res. M.O. £100.
 Birmingham, Selly Oak Hospital.—Cas. O. At rate of £200.
 Boothe Borough Hospital.—Hon. Radiologist.
 Bristol General Hospital.—H.S. At rate of £30.
 Bristol Royal Infirmary.—Hon. Asst. Surg. Also Hon. Anæsthetist.
 Buxton, Devonshire Hospital.—Asst. H.P. At rate of £150.
 Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
 Also Res. Anæsthetist. Also H.P. At rate of £180 and £130 respectively.
 Cambridge University, Pathological Laboratory.—John Lucas Walker Studentship. £300.
 Canterbury, Kent and Canterbury Hospital.—Hon. Radiologist
 Cottingham, E. Yorks. Tuberculosis Sanatorium.—Res. M.O. £185.
 Derby, Derbyshire Royal Infirmary.—Two H.S.'s. Each at £150.
 Also Hon. Asst. Ophth. Surgeon.
 Drednought Hospital, Greenwich, S.E.—Med. Supt. £300. Also H.P. and H.S. Each at rate of £110.
 Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.
 East Ham Hospital, Shrewsbury-road, E.—Hon. P.'s and S.'s.
 East Ham Memorial Hospital, Shrewsbury-road, E.—Res. M.O. and Res. H.P., and Cas. O. At rate of £150 and £100 respectively.
 Exeter City Mental Hospital.—Asst. M.O. £350.
 Guy's Hospital, S.E.—Asst. Physician.
 Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—H.S. Also H.P. At rate of £100.
 Hong-Kong University.—Chair of Medicine. £300.
 Hospital for Epilepsy and Paralysis, Maida Vale, W.—Med. Reg. £100.
 Hospital for Sick Children, Great Ormond-street, W.C.—Surgeon.
 Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H.P. At rate of £135.
 Indian Medical Service.—Recruitment of European Officers.
 Jewish Health Organisation of Great Britain, 4, Upper Gloucester-place, N.W.—Medical Supervisor of Jewish Evening Schools. 30s. per visit.
 Kensington, Fulham and Chelsea General Hospital, 194, Finborough-road, Earl's Court, S.W.—Res. M.O. At rate of £100.
 Leeds Jewish Herzl-Moser Hospital.—Res. M.O. £50.
 Leicestershire County Council.—Asst. Tub. M.O. £600.
 Liverpool, Hahnemann Hospital, Hope-street.—Stipendiary M.O. At rate of £125. Res. M.O. At rate of £100. Also Clin. Asst.
 London Jewish Hospital, Sleepy Green, E.—Cas. O. At rate of £150.
 London Lock Hospital, 91, Dean-street, W.—H.S. At rate of £200.
 Luton Borough.—Asst. M.O.H., &c. £600.
 Manchester, Anconis Hospital.—Orthopaedic Registrar. Also Med. Registrar. £100.
 Manchester Babies Hospital.—Jun. Res. M.O. At rate of £50.
 Manchester, Barnes Convalescent Hospital, Chadde.—Res. M.O. £250.
 Manchester, Salford Royal Hospital.—Res. Surg. O. £200. H.P.'s and H.S.'s, also Cas. H.S. Each at rate of £125.
 Manchester Victoria Memorial Jewish Hospital, Cheetham.—Hon. Anæsthetist. £50.
 Metropolitan Hospital, Kingsland-road, E.—Res. Cas. O. At rate of £100.
 National Hospital, Queen-square, W.C.—H.P. £150.
 Paddington Green Children's Hospital, W.—Surgeons.
 Plymouth City Mental Hospital, Blackdon, near Ivybridge.—Jun. Asst. M.O. £300.
 Poplar Hospital for Accidents, East India Dock-road, Poplar, E.—2nd med. O. £175.
 Radruith, Cornwall, West Cornwall Miners' and Women's Hospital. Radiographer.
 Royal Northern Hospital, Holloway, N.—Obstetric Physician.
 Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.P. At rate of £100.
 St. Helen's, County Borough.—Deputy M.O.H. £700.
 St. Mary's Hospital, W.—Med. Supt. £100. Also Medical Registrar. £200.
 St. Mary's Hospital, Institute of Pathology and Research, W.—Research Studentship. At rate of £200.
 St. Thomas's Hospital, S.E.—Res. Asst. Physician, also Medical Registrar.
 Sheffield, Jessop Hospital for Women.—Three Asst. H.S.'s. Each at rate of £100.
 Sheffield, Royal Infirmary.—Jun. Aural and Ophthalmic H.S. At rate of £50.
 Streatham, Royal Ship Infirmary.—Res. H.S. Also Res. H.P. Each at rate of £160.
 Southampton, Parlo Infirmary, Shirley Warren.—Second Res. Asst. M.O. £275.
 Tisbury Hospital.—Med. Supt. £250.
 Truro, Royal Cornwall Infirmary.—H.S. £170.
 University of London, South Kensington, S.W.—Geoffrey Durcan Travelling Studentship in Ophth.-Laryngology. £450.
 Victoria Water, Surrey, Holloway Sanatorium.—Jun. Asst. M.O. £275.
 West African Medical Staff. M.O. £800.
 Willesden General H. of 13.—Clin. Asst.
 Winchester, Hampshire County Council.—Asst. County M.O.

Notes, Comments, and Abstracts.

THE HEALTH OF THE UNDERGRADUATE.

THE "Essai sur l'hygiène universitaire," which Dr. Robert Jacquet, of the University of Nancy, has just published, fills a gap and fills it very ably. The author is described on the cover as the President of the French National Union of Students, and Mr. Herriot, who has supplied a preface, refers therein to his "youthful ardour," whilst there is internal evidence of ten years' work in the special field which he has chosen, so one is justified in concluding that he is exceptionally well placed to know his subject. He has, at all events, mapped out the field in masterly fashion and has not contented himself with pointing out deficiencies: in every case he suggests remedies. The book describes the situation of the university student in France and is therefore only partially applicable to residential universities in England, but so much of what is described does apply to our own universities that it should stimulate thought on both sides of the Channel.

Part I., entitled "The Future Student," describes the health conditions surrounding the French collegian before he enters a university—the overloaded curriculum, the lack of physical exercise, the poor teaching of hygiene, the total exclusion of sex hygiene. The remedies suggested are obligatory medical examination, classification according to physical ability, proper times for physical exercises and sports, and systematic teaching of hygiene including lessons in sex hygiene by a doctor. Dr. Jacquet puts in a special plea for vocational guidance, and he considers that the right time for the tests and vocational examination to take place is at the age of 16 to 18, when the boy (girls are not mentioned in this book) leaves his college or lycée before entering the university.

Part II. describes the conditions surrounding the undergraduate on arrival at the university. Often he lodges in poor furnished rooms in the oldest quarter of the town (the author remarks on the similarity between a map of Nancy showing the worst centres of tuberculosis and one showing the quarters where most students' lodgings are advertised). Fortunately students' hostels are now springing up. In Paris the fine *Cité universitaire*, international in conception, is already inhabited in part; and at Nancy the university is putting up a similar residential hostel for its students in a park on the outskirts of the town. Poorly housed as the undergraduate is, he is often worse fed. Here the suggested remedy is to have coöperative restaurants, one of which is already working in Paris. Having fed and housed the student, the next thing is to provide him with exercise. The chapter devoted to the need for sports in universities might be skipped by the English reader, were it not that the author has inserted a warning against what he calls "athletic exhibitionism." The term is eloquent.

Health teaching in the university should continue and supplement that given at school, and should include lectures on public health and industrial hygiene. To the objection that undergraduates will not attend such lectures, Dr. Jacquet replies that the Students' Union at Nancy organised a series of them with the greatest success and that the halls were crowded. Medical students, he adds, should be obliged to attend lectures on public health; the need for such insistence is in itself astounding.

The first three chapters of Part III. describe the Swiss University Sanatorium at Leyrin, the projected international university sanatorium, also at Leyrin, and the sanatorium in the French Alps belonging to the French National Union of Students. Plans and illustrations add interest to the text. One can only hope that the international sanatorium will cease soon to be a plan and become a reality. English students are admitted to the Swiss sanatorium as far as numbers permit: the international sanatorium is to have 200 beds. Hardly less interesting is the author's description of a university health centre and dispensary, as he conceives it and as he hopes to have one erected in the University of Nancy. The plans, which have been approved, are published in this book. With this very concrete suggestion the author ends his vigorous essay. The reader will agree with Mr. Herriot when he says: "What is the good of training minds, of raising them to the highest scientific levels, if bodily weakness renders these young people's efforts sterile, so that all the sacrifices made by the family and community for their education are made in vain?"

OSLER AS EPIDEMIOLOGIST.

Is amplification of his remarks made at the meeting of the Osler Club last July, to which we alluded in a previous issue, Dr. J. D. Rolleston in a recent paper emphasises the keen interest taken by Sir William Osler in the study of epidemic diseases, an interest doubtless inspired to

some extent by the fascinating history connected with many of them. His familiarity with the work of the earlier epidemiologists is illustrated in his text-book and miscellaneous writings, particularly his essay on "Some Aspects of American Bibliography." Although small-pox, cerebro-spinal fever, and venereal disease formed the subject of some of his more important addresses, typhoid fever and tuberculosis were the infectious diseases to which he devoted most of his attention. The importance which he attributed to typhoid fever, which owing to the heavy toll it levied among young persons, he called "the minotaur of infectious diseases," is shown not only by its occupying the first place in his text-book, but also by his dictum that a student could learn most of medicine and a good deal of surgery—the latter mostly at the patient's expense—by the study of this disease alone. The insanitary conditions responsible for the outbreaks of typhoid fever which was rife in America, particularly at Baltimore, when Osler was professor of medicine at Harvard, frequently provoked a protest from him. The incidence of typhoid fever, he maintained, was the sanitary index of the community, and in the matter of purification of their large towns he accused the United States of being a generation behind Europe. Many years later, shortly after the outbreak of the war, he urged the necessity of antityphoid inoculation, and denounced the "sons of Belial" who were trying to oppose the measure. In like manner his conviction of the value of vaccination against small-pox is illustrated in a characteristic passage in his essay entitled "Man's Redemption of Man," in which he issues a "Mount Carmel-like challenge to any ten unvaccinated priests of Baal." Osler's interest in tuberculosis assumed a very practical form. In 1902 he was responsible for the establishment of the first tuberculosis dispensary at Baltimore. He also took an active part in the campaign against tuberculosis in Philadelphia and in England, where he helped to form the National Association for Prevention of Consumption in 1903, and started an Oxford branch of the Association in 1910, while it was only his fatal illness which prevented him delivering an address before the Association in 1919. His interest in epidemic disease was maintained until the end. In June, 1918, he paid a special visit to the London Hospital to see the first cases of lethargic encephalitis, and a few months before his death he approached the Foreign Office for concerted medical action to deal with the deplorable sanitary conditions in Vienna which were a menace not only to German Austria but also to the rest of Europe.

HOSPITAL CONTRIBUTORY SCHEMES.

A SUGGESTION FOR A COMBINED APPEAL.

IN the course of an instructive address on the Future of the Voluntary Hospitals to a meeting of hospital officers held at Liverpool on Nov. 23rd, Captain J. E. Stone, F.S.A.A., remarked on the excellent field offered by contributory schemes for the purpose of raising additional revenue. They have, he said, become recognised as a bountiful source of income, and they have the merit of increasing the interest of the public in the work of the hospitals. Schemes of one sort or another are now very numerous all over the country: generally the basis is the same, a weekly contribution, but beyond this there is little or no uniformity. It now appears that the time is opportune for the consideration of some universal contributory scheme with distribution on the basis of the work done for members. The scheme would be available to the community as a whole, a sort of insurance scheme whereby weekly or other payments in time of health would ensure hospital treatment in times of sickness. Under a co-ordinated scheme the voluntary hospitals would themselves be co-ordinated and a contributory scheme carried on under the guidance and direction of an advisory body of voluntary hospitals would seem to possess attractions and open up the possibilities of a considerable increase in revenue.

Generally appeals are not, Captain Stone remarked, so successful to-day as they were a few years ago. Ballots, "stunts" of various kinds, emotional propaganda. "S.O.S." messages, flag days, and all the hundred and one other methods used by the voluntary hospitals have had their day. They still bring in some revenue, but it is a question whether they have not done more harm than good in other directions. There is growing up a feeling of hard-heartedness—the public is sick and tired of being told that one hospital is falling down, that another cannot pay its meat bill, and that another is closing beds. It is growing acclimatised to even the most heartrending appeal. Every person whose name appears in a directory is deluged with charitable appeals from hospitals not only in his own interest but from larger ones in the surrounding area, and from others, too, hundreds of miles away.

A combined appeal on a national basis, run by county associations, would be better, in Captain Stone's opinion, than all these smaller efforts. A soundly conceived contributory scheme for the whole country offers in fact the best solution of the financial problem as far as the voluntary hospital is concerned.

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(Continued from p. 1166.)

THE following is the text of the official bulletins which have been issued during the King's illness by Sir Stanley Hewett and Lord Dawson.

THURSDAY, NOV. 29TH. 10.15 A.M.

The King has passed a quiet though rather sleepless night. The infective process is being held in check. 7.30 P.M. The King has had a quiet day with some sleep. Otherwise conditions remain unchanged.

FRIDAY, NOV. 30TH. 12.20 P.M. (This bulletin is signed also by Sir Humphry Rolleston.)

The inflammation of the lung and pleura shows some improvement and the temperature is on a slightly lower level. It must be noted that the time of possible exacerbation of the infection has not yet passed, and in any case progress must be slow.

8.15 P.M. The condition of His Majesty the King shows no change this evening.

SATURDAY, DEC. 1ST. 10.30 A.M.

In spite of His Majesty having passed a fair night, there has been a slight rise in the temperature since yesterday. The general condition remains unchanged.

8.30 P.M. The King has had rather a disturbed day, with short intervals of sleep, and is therefore somewhat fatigued.

SUNDAY, DEC. 2ND. 11.15 A.M.

The King has had rather a restless night. This morning the temperature is lower, and the infective process shows some improvement. The general strength, though at present adequate, is at this stage of the illness being taxed.

8.20 P.M. His Majesty has had a quieter sleep during the day. The infective process has continued to diminish and the temperature to-night is 100°. At the same time there is a decline in the strength of the heart which causes anxiety.

MONDAY, DEC. 3RD. 12.10 A.M. (Signed also by Sir Farquhar Buzzard and Dr. L. E. H. Whitby.)

His Majesty the King has had some sleep during the last three hours. A further consultation confirms the opinion expressed in the last bulletin, and, in spite of the improvement in the lung, anxiety concerning the strength of the heart persists.

10.30 A.M. The King has had three hours of quieter sleep since the issuing of the last bulletin. The temperature is now 99.8° and there is slight improvement in the general condition.

MONDAY, DEC. 3RD. 8.15 P.M. (Signed also by Sir Farquhar Buzzard and Sir Humphry Rolleston.)

The slight improvement in His Majesty's condition noted this morning has been maintained. The temperature is nearer normal, but it is necessary to emphasise that the anxiety concerning the heart still persists.

TUESDAY, DEC. 4TH. 10.30 A.M.

The King has passed a quieter night. Though the anxiety concerning the heart must continue, the improvement noticed last evening is so far satisfactorily maintained.

3.30 P.M. His Majesty the King passed a quiet morning. Though the temperature is now 100.2° the slight improvement in the general condition noted in the last bulletin is maintained. (Signed also by Sir Farquhar Buzzard, Sir Humphry Rolleston, and Dr. Whitby.)

8.30 P.M. The rise of temperature noted in this afternoon's report persists and as a result the King is rather less comfortable. Otherwise conditions remain unchanged.

WEDNESDAY, DEC. 5TH. 10.30 A.M.

The King has passed a fair night. There are reasons to hope that the recrudescence of the infection which caused the last rise of temperature is being moderated. 8.15 P.M. Though the King has had a quiet day, the temperature has risen to a point higher than at the same hour last evening, showing that the recrudescence of the infection is still active. The strength is maintained. (Signed also by Sir Farquhar Buzzard and Sir Humphry Rolleston.)

Oliver-Sharpey Lectures

ON AN EXPERIMENTAL STUDY OF CERTAIN VISCERAL SENSATIONS.

Delivered before the Royal College of Physicians of London

By E. P. POULTON, D.M. OXF.,

FELLOW OF THE COLLEGE AND PHYSICIAN TO GUY'S HOSPITAL.

LECTURE I.*

Delivered on May 1st, 1928.

BEFORE beginning my lectures I should like to acknowledge how much help I have received from others in their preparation. By far the greater part of the work has been joint work, and I should like specially to thank Dr. W. W. Payne, formerly Parsons Research Fellow at Guy's Hospital, for his willing and conscientious coöperation in the greater part of it.

HISTORICAL.

The subject of visceral sensation is a wide one, and has been investigated from many points of view. Thus, if pain is taken for consideration, as it is the sensation that has been dealt with most frequently, there is the problem as to whether it is felt in the organ itself, and whether it is at the same time referred to the external coverings of the body as was originally suggested by Ross.¹ There is the detailed work of Head² on the relation of these referred areas of pain to the underlying viscera by means of nervous connexions running through the spinal cord; there is the closely related work of Mackenzie³ and his view that all visceral pain is felt superficially in the skin, voluntary muscles, and loose underlying connective tissue of the body wall. These problems have been considered time and again by different authors, and the general conclusion came to was that Ross was correct in his original presentation of the subject.

Then, again, there is the problem of the uninsulated character of the pain nerve-endings, as described by Trotter⁴; there are the problems concerned with afferent paths of sensation, such as McDowall⁵ has touched upon for visceral sensation, and Adrian⁶ also has dealt with as regards common and visceral sensation. In this connexion it is right to emphasise how obscure at present are the problems concerned with visceral sensation. At least it is admitted as regards other sensations that light waves, sound waves, chemical agencies, mechanical strain with deformation of end-organs, are adequate stimuli for sight, hearing, taste, touch, pressure, and muscle sense. But as far as visceral sensation is concerned, there is no general agreement even as to the nature of the stimulus itself. It is to this latter problem that these lectures will be primarily devoted.

Looking backwards it is easy to see that if again pain is taken as the subject of inquiry, two main theories have been advanced as to its nature. Magendie,⁷ one of the classical investigators, described the severe pain which accompanies the swallowing of a large bolus as being produced by the distension of the nerve-fibres of the pectoral part of the œsophagus. While Haller⁸ had observed that the bile-duct and ureter were insensitive to mechanical stimuli of various kinds, though they produce very intense sensations during the passage of gall-stones or renal calculi, Sherrington⁹ has pointed out that the stimuli to produce sensation in viscera must be adequate, or, to be precise, mechanical stimuli to produce pain are distensible. This is the point of view taken up by Hurst¹⁰ in his well-known Goulstonian Lectures, and he has gone further in suggesting that all types of visceral sensations, except hunger, are of the same nature, and are produced by tension of different degrees on nerve-endings in the muscles.

A second theory of visceral sensation was originated by Cannon and Washburn¹¹ in their well-known paper on hunger. Defining hunger as a dull ache or gnawing sensation referred to the lower mid-chest region and the epigastrium, they found that the pangs were associated with those gastric (and œsophageal) contractions that Boldireff had previously described. However, they state that almost invariably the contraction reached its maximum position before the record of the sensation was started, drawing the conclusion that the contraction caused the sensation, and that it was not the hunger that caused the contraction. Carlson and his co-workers¹² have greatly amplified these observations. Again, Mackenzie¹³ has argued that vigorous peristalsis is the cause of visceral pain, and there is a well-known clinical observation of his on a patient on whom he was operating when pain was produced every time a peristaltic contraction of the bowel converted it into a thick fleshy rod.

Hurst,¹⁴ while stating that peristalsis is not itself a cause of pain, has combined both these theories by suggesting that in both stomach and intestine and other hollow viscera a downward wave of peristalsis produces a ballooning of the viscus just below against some point of resistance such as the spasm or achalasia of a sphincter or a foreign body. He believes that the ballooning is responsible for the pain, since the nerve-fibres in the muscle are stretched. Cannon's graphic description¹⁵ suggests that pain of this kind may perhaps occur in intestinal obstruction. He says:—

"The moving constrictions were evidently powerful, for as they advanced the walls of the canal in front were bulged widely by the compressed contents; and when the peristaltic ring could no longer withstand the pressure it was causing, the contents squirted back through the advancing ring for some distance along the gut."

But evidence will be given that the commonly occurring gastric pain is certainly not due to movements of this nature.

POSTURE AND TONE.

Sherrington¹⁷ has applied his conception of posture to the viscera. The size or volume of viscera may vary without necessarily causing much alteration of the internal pressure. His illustrations were taken chiefly from Mosso and Pellacani's work on the bladder and Cannon's work on the stomach. Increase in posture is brought about either by the lengthening of the muscle-fibres in the wall or by the sliding of muscular sheets over one another, so that the thickness of the wall is lessened and the capacity is increased; but while posture is a function easily defined, let us beware in this connexion of the expression "postural tone," since I shall hope to show that tonus or tone is another different property of smooth muscle as readily defined and equally important. In order to obtain a graphic record of the pressure in the œsophagus Payne and I¹⁸ introduced into the latter a toy balloon which was tied onto the end of a long œsophageal rubber catheter. The other end of the catheter was connected with (1) a funnel and water reservoir so that the volume of air in the balloon could be varied; and (2) a water manometer, the other end of which was connected to a Brodie's bellows, so that the excursions of the manometer could be recorded on a kymograph. In recent experiments by Ride and myself the Brodie's bellows has been replaced by a very small form of recording spirometer, made on the principle devised by Krogh.¹⁹ The experiments were carried out in the lower part of the œsophagus where the muscle is unstriated and the volume of air used was never more than the capacity of the bag—i.e., 50 c.cm. or 200 c.cm., as the case might be. This means that outside the body the bag could accommodate the amount of air used in the experiments without any increase of its internal pressure while its walls remained flaccid. Inside the œsophagus the bag acted as a stretching force, because, owing to the smaller size of the œsophagus, the bag could not

* The preliminary remarks on the foundation of the lectures have been in the Lecture II, with all the references. Vol. 1928, p. 100, 101.

* This apparatus is supplied by C. F. Palmer, Ltd., Filton, London.

accommodate the amount of air introduced and yet preserve its original spherical shape. It became fusiform.

The advantage of our procedure is that the pressure reached in the bag represents the pressure actually being exercised by the oesophageal muscle. Fig. 1 shows the pressure in centimetres of water recorded in the oesophagus by a rubber bag of 50 c.cm. capacity, when the contents of that bag was increased (at the arrows) from 10 c.cm. up to 45 c.cm. The most striking appearance is the regular succession of peristaltic waves lasting from about 3 to 8 sec. each. These waves may be said to start from a base line which itself slowly varies and they reach a level of over 40 cm. This level tends to remain constant

larger. In the case of a cylinder the relation between tension T and pressure p and radius r is given by the equation $T = pr$, so that when the pressure remains the same the tension increases with the radius. It is surely a mistake to identify high tone with low tension; but that is what the doctrine of the "tonus ring" has done.

A THEORY OF VISCERAL PAIN.

The theory of visceral pain which has been put forward as the result of our experiments is that pain is due to the stretching with consequent deformity of the nerve-endings subserving the sense of pain, which are situated in the walls of the viscus. When the volume of air in the bag at the lower end of the

FIG. 1.

The lower tracing is respiration, inspiration being shown by an upstroke on the respiratory tracing, and a downstroke on the oesophageal tracing. Time in seconds. Simultaneous points are shown by small white strokes. The other figures are arranged similarly.

even though the air in the bag is increased and the base line is rising all the time. A. R. Thompson¹⁹ has obtained similar curves from the bladder. The term systolic pressure may quite well be applied to the tops of these peristaltic waves on the a. of the heart and the term diastolic pressure to the base line. (This is a wider use of these terms than suggested recently by Alvarez.²⁰) As a visceral sensation is concerned, it is the diastolic pressure that is important, or more correctly tension of the muscle during diastole. It is this value that may be defined as the tone of plain muscle. Fig. 1 shows that as the tone rises the peristaltic pressure waves are at first increased; but then they get less, and, finally, they disappear away completely as the tone reaches a maximum.

Unfortunately the term "tonus ring" has been applied to other conditions for which it is not applicable, and confusion has arisen. Cannot it be said that in various places the sustained contraction with interference and waves of contraction point and passed in succession dilated parts. He called the contraction a tonus ring, although tension of the muscle at the tonus was not observed. Went a circumferential contraction this.

oesophagus is increased by stages the diastolic pressure and consequently the tone rises, and at a certain point pain is felt. Thus in the case of W. W. P., with 10 c.cm. in the bag the pressure was -5 cm.; with 30 c.cm. it was 15 cm.; with 40 c.cm. it was 17-21 cm., and pain was felt continuously.

Given a state of tension, a sensation, an increase in tension, a third mechanism which

The postural, more relaxed, to act as a falls. For diastolic was no when the

increased, moderated, the bag it, and pressure c.cm. in 20 cm., three inning never pain intents the asing

tion. in to be work

trying to drive the bag downwards. In spite of the tension on the pain-endings falls because the diameter of the viscus diminishes. In other

words, the muscle by contracting takes the tension off the various structures. If the peristaltic wave succeeds in removing the foreign body the pain will disappear entirely: but if the bag is not in position by an attachment outside the mouth the wave must be ineffective, and if it passes by the diameter of the bag will come large pain and pain become re-established. It follows that pain may be felt during

the relaxation of a peristaltic contraction. Fig. 2 provides a proof of this thesis. Two bags were placed in the oesophagus, one just above the other: the upper bag (upper tracing) contained 10 c.cm. of air, the lower bag was empty. At the small white mark 40 c.cm. of air was suddenly introduced into the lower bag. A series of peristaltic waves passed down causing a rise of pressure in each bag in turn. The introduction of air caused a slight continuous pain, which showed exacerbations at regular intervals indicated by descent of lever. It was observed that the exacerbations of pain came on suddenly: but the sensation faded off somewhat indefinitely. It is clear that the exacerbation was first noticed during the relaxation after a peristaltic contraction, while the contraction itself definitely diminished the sensation. These peristaltic contractions were quite unnoticed by the patient. They were not connected with swallowing or any movement of the throat. Consequently they were an example of what Meltzer¹ has described as secondary peristalsis. In view of the truly surprising nature of this and other similar results we thought it advisable to try to get photographic evidence of the

appearance of the oesophagus during experimental pain. An air bag was made out of two rubber balloons of the same size by squeezing one inside the other. The space between the two was filled with a suspension of bismuth, and the necks tied one over the

other on to a catheter. On filling the inner balloon with air the bismuth was spread over its surface, and an air bag was obtained with its walls opaque to

FIG. 2.

FIG. 3.

Fig. 3 (A) is an outline of the bags in situ. The walls were well defined, so that during the two or three seconds' exposure the oesophagus had remained fairly quiet. The lower bag was then filled with 30 c.cm. of air (B), which dilated but did not lengthen it, while the upper bag was practically unchanged. Pain of medium intensity was experienced. After another experiment, which need not be described here, 40 c.cm. air was introduced into the lower bag, while the upper bag still contained 10 c.cm. (D). Pain of maximum intensity was felt about one second before the exposure of the plate began; it then steadily diminished, and was nearly but not quite minimal by the end of the exposure. In the plate it was almost impossible to see the lower bag at all except for the dark shadow of the bismuth at its lower end which lay beneath the dome of the right diaphragm. Measurement shows that the lower bag was increased in length by 1 cm. and the upper bag by 9 mm. The indistinctness of the outline indicated that movement was actually occurring during exposure, and since these movements resulted in elongation of the bags they were clearly due to the passage of a peristaltic wave which successfully squeezed the foreign body and so caused a diminution in the pain produced by it.

(3) Stretching of the oesophageal wall was an obvious factor in causing pain in such experiments a third increase the intensity of the pain: it is due to the holding up of the peristalsis.

This was investigated by means of a rubber bag

accommodate the amount of air introduced and yet preserve its original spherical shape. It became fusiform.

The advantage of our procedure is that the pressure reached in the bag represents the pressure actually being exercised by the oesophageal muscle. Fig. 1 shows the pressure in centimetres of water recorded in the oesophagus by a rubber bag of 50 c.cm. capacity, when the contents of that bag was increased (at the arrows) from 10 c.cm. up to 45 c.cm. The most striking appearance is the regular succession of peristaltic waves lasting from about 3 to 8 sec. each. These waves may be said to start from a base line which itself slowly varies and they reach a level of over 40 cm. This level tends to remain constant

larger. In the case of a cylinder the relation between tension τ and pressure p and radius r is given by the equation $\tau = pr$, so that when the pressure remains the same the tension increases with the radius. It is surely a mistake to identify high tone with low tension; but that is what the doctrine of the "tonus ring" has done.

A THEORY OF VISCERAL PAIN.

The theory of visceral pain which has been put forward as the result of our experiments is that pain is due to the stretching with consequent deformity of the nerve-endings subserving the sense of pain, which are situated in the walls of the viscus. When the volume of air in the bag at the lower end of the

FIG. 1.

The lower tracing is respiration, inspiration being shown by an upstroke on the respiratory tracing, and a downstroke on the oesophageal tracing. Time in seconds. Simultaneous points are shown by small white strokes. The other figures are arranged similarly.

even though the air in the bag is increased and the base line is rising all the time. A. R. Thompson¹⁹ has obtained similar curves from the bladder. The term systolic pressure may quite well be applied to the tops of these peristaltic waves on the analogy of the heart and the term diastolic pressure to the base line. (This is a wider use of these terms than that suggested recently by Alvarez.²⁰) As far as visceral sensation is concerned, it is the diastolic pressure that is important, or more correctly the tension of the muscle during diastole. It is this value that may be defined as the tone of plain muscle. Fig. 1 shows that as the tone rises the peristaltic pressure waves are at first increased; but then they get less, and, finally, they may die away completely as the tone reaches a maximum value.

Unfortunately the term tone has been applied to other conditions for which it is unsuitable, and much confusion has arisen. Cannon,¹⁶ for instance, observed that in various places the intestine underwent a sustained contraction with lessening of the circumference and waves of contraction originated at this point and passed in succession over neighbouring dilated parts. He called the point of sustained contraction a tonus ring, although he realised that the tension of the muscle at the tonus ring was lower than it was elsewhere, where the circumference was

oesophagus is increased by stages the diastolic pressure and consequently the tone rises, and at a certain point pain is felt. Thus in the case of W. W. P., with 10 c.cm. in the bag the pressure was -5 cm.; with 30 c.cm. it was 11-15 cm.; with 40 c.cm. it was 17-21 cm., and pain was felt continuously.

Given a state of pain due to this cause there are two ways in which the viscus may react so as to diminish the sensation, and there is a third mechanism which will increase the pain.

(1) *The posture may be increased*, so that the bag is now more readily accommodated inside it, and ceases to act as a stretching force, and the pressure inside it falls. For instance, in Fig. 1b with 45 c.cm. in the bag the diastolic pressure varied from 14-28 cm., and there was no pain recorded at all; but three days later, when the bag was filled at the beginning with 40 c.cm., the diastolic pressure was never below 24 cm., but was often over 30 cm., and pain was felt most of the time. In Fig. 1 the contents of the bag had been increased gradually, and the oesophagus had had time to adapt itself by increasing its posture.

(2) *The muscle may undergo a systolic contraction*. Of course, this materially increases the pressure in the bag, and the tension of the muscle will also be greatly increased because the muscle is doing work

at which the pain due to a distending bag as in Fig. 5 should become lessened: (1) during the short, sharp relaxations of the muscle above the bag, when the zonal strain would be relieved; and (2) at the peaks on the lower tracing, when there would be some shortening of the stretched oesophageal wall by means of active muscular contraction.

Similarly, there are two points in the cycle at which the intensity of the pain would become increased: (1) at the beginning of systole, when the oesophagus has contracted above the distending bag, but has not yet succeeded in compressing it, so that zonal strain is established; (2) at the end of systole, when the active contraction has passed off and the condition of stretch becomes re-established.

Both Payne and myself took part in these experiments, but there was this difference between us—viz., that on the whole it was much easier with the apparatus used to produce severe pain in him than in myself. Further, W. W. P. is inclined to suffer from indigestion, which is not the case with myself. Radiograms of the lower part of the oesophagus immediately after swallowing a mouthful of barium emulsion showed that my oesophagus was the wider of the two, the maximum diameter for E. P. P. being 2.4 cm. and for W. W. P. 2 cm. With a given volume of air in the bag a bigger excitation might be expected in the latter case. On comparing the pressure curves from the two subjects there was a striking difference, since in the case of W. W. P. single large contractions were often recorded when the tonus remained rather low (see Fig. 2), while in the case of E. P. P. the tonus was increased and the contractions were often multiple, and not very large (Fig. 1). The maximum systolic pressures were about the same in both cases.

When the pain produced by an air bag was of short duration it was recorded during the relaxation stage of a peristalsis, and when the pain was of longer duration it began during relaxation (Fig. 2), which suggests that tension is most likely to be exerted on the pain-endings when the fall of pressure is large and rapid. We have suggested that high tonus is itself responsible for pain; but the steady state of tension

which fix posture, which have been described by Sherrington and Bayliss.

The character of the pain produced in our experiments varied according as it was continuous or intermittent. In the former case it had a burning character, and was reminiscent of heartburn. An unpleasant sensation referred to the throat, but also situated deeply at about the level of the suprasternal

FIG. 6.

notch, was present if the bag was high up in the oesophagus. If it was lower down the pain was usually referred to the costal angle and the lower part of the sternum in the mid-line. When the pain was intermittent it had what was best described as a gripping or gripping character, and the relation of the two types of pain was well seen in an experiment on W. W. P. on May 25th (Fig. 6). At first with 45 c.cm. in the bag continuous severe burning pain was noticed. The diastolic pressure was 30 cm., and there were only respiratory variations. A swallow was then taken (s) and this was followed by a series of peristaltic contractions, each of which caused diminution in the pain and converted it from a burning pain into a gripping pain. Later on the contractions stopped, and the pain again became continuous and burning

FIG. 5.

due to this cause may not be so painful as the rapid increase of tension that occurs during the relaxation when the muscle is ceasing to bear the greater part of the strain. Hence a condition of high tonus may have a real advantage in that it checks the relaxation in its course, and from this point of view it is tempting perhaps to try to draw some analogy between the type of plain muscle as we have defined it and the check or catch functions of certain plain muscles

We noticed the same thing on another occasion, when after a period of severe continuous burning pain without contractions a little air was let out of the bag. Large peristaltic contractions then appeared which made the pain intermittent, and so gave it a gripping character. A recent observation by L. T. Hild and myself suggests that the burning element of the pain may be due to simultaneous superficial vaso-dilatation.

about the size of a large finger-stall which was placed inside an inextensible linen case and then tied on to a stiff catheter. This was placed inside the lower part of the œsophagus and arrangements were made so that water could be forced into the bag under such a high pressure as to prevent any possible squeezing of it by the œsophageal muscle. An ordinary toy balloon containing 10 c.cm. air and attached to a manometer and recording apparatus was also swallowed, so that the behaviour of the œsophagus above or below the part stretched could be investigated. Fig. 4 gives a tracing from the toy balloon when it was situated just above the incompressible

contraction was taking place. At first sight this in itself might be considered enough to cause the pain, and so far there is no absolute proof that this was not the case; but on general principles it is extremely unlikely. For instance, to take an example from skeletal muscle, a tug-of-war is not an essentially painful form of exercise. In the case of the uterine plain muscle the intermittent contractions that occur throughout pregnancy are not painful. Every beat of the heart is associated with an isometric contraction of the ventricular muscle up to the time when the sigmoid valves are opened and blood becomes discharged. Hence it is necessary to look for another

FIG. 4.

bag. At w 17 c.cm. of water were suddenly forced in and a series of contractions began and pain was felt at once; it was continuous although it varied in intensity. It was worse during the contraction and was so bad that it was impossible for the subject (W. W. P.) to keep the lever down all the time. He found it easier to move it up and down so that the rapidity of the movement indicated the extent of the pain. At a point marked s he swallowed experimentally and pain became still worse, so that eventually a little water, about 5 c.cm., had to be let out. This is marked by the depression at x. The effect of the swallow was to cause a sustained contraction of 27 seconds' duration at a pressure of 40 cm. It might almost be called a tetanus. There was a peristaltic wave after the water was finally let out at z, and then the œsophagus became quite quiet, showing only respiratory movements and a swallow (s) taken at the end of the experiment was unaccompanied by any painful sensation.

In the next experiment the toy balloon was placed below the incompressible bag. On forcing in the water continuous pain was noticed; but it was not as bad as last time because the bag was probably not filled up so tightly. The only effect on the lower bag was a slight increase in diastolic pressure; but none of the peristaltic waves that were demonstrated in the previous experiment succeeded in getting past the incompressible bag, so as to be registered below. Respiratory movements were registered satisfactorily below, so that there can have been no squeezing of the connecting tube where it passed by the incompressible bag. As soon as the water was let out the pain stopped and two peristaltic contractions were now recorded without any painful sensation.

The theory that I have put forward is that visceral pain is due to stretching, but Fig. 4 shows that this theory alone is incomplete because, owing to the incompressibility of the bag, the amount of stretch produced by it must have remained constant from the time the water was put in until a small amount was let out; and yet the pain varied, becoming worse when a peristaltic wave was recorded immediately above the bag responsible for the pain. No doubt during peristalsis the top of the incompressible bag was being squeezed hard by the œsophageal muscle without any shortening of its fibres. An isometric

explanation of the increase of pain during contraction in Fig. 4. This is provided by another experiment in which two air bags were used (Fig. 5). The upper one contained 5 c.cm. and into the lower one 70 c.cm. air (the full capacity of the bag) were suddenly introduced. Pain of moderate severity was experienced immediately. Minor variations in pain were felt; but not recorded. An involuntary swallow was taken immediately the lower bag was filled and the pressure in both bags at once rose. L, M, N, R are simultaneous points on the tracing and represent the apices of peristaltic waves. The large depressions in the upper tracing are evidently due to the temporary relaxing or inhibition of the muscle that always precedes peristalsis—very obvious in this case because all the rest of the time the muscle was held in a state of sustained contraction similar to that shown in Fig. 4. The pressure exerted by the œsophageal wall was permanently increased at the site of both bags; but the diastolic pressure was much lower at the higher bag and its value is indicated by the pressure registered during the short inhibitory periods—under 20 cm. Except for these short inhibitions the muscle at the upper bag remained all the time in systole at about 40 cm. pressure. However, at the site of the lower bag which acted as the foreign body causing the disturbance, the muscle was being stretched and the peristaltic wave did not succeed in making any impression on the bag except for short periods of time in the middle of systole, so that except at the peaks L, M, N, R the pressure remained during systole at the diastolic value (about 40 cm.). When such an opposite state of affairs is taking place in two contiguous parts of the same organ it is not difficult to see that during systole a state of strain may be set up on the pain-endings in the zone between the muscle contracted down above and the muscle dilated and stretched just below. It is to this strain that the term painful spasm may be applied when a renal calculus or a gall-stone is held up in its progress along the duct, and no doubt this factor is also present in the violent peristalsis of intestinal obstruction described by Cannon, though possibly Ilurst's hypothesis of the muscular wave itself producing distension below has an application in this special case.

Summarising, it may be pointed out that on our theory there are two points in the cycle of peristalsis

meal the pressure was lower, while the record remained flat and the patient was quite comfortable with no sensations.

We carried out further observations on this patient to find out the relation between the contractions of the stomach and the duodenum by means of two bags each attached to a manometer, while the excursions of both manometers were recorded on a kymograph. It was found that the systolic rises of pressure in the stomach and duodenum were similar to one another; but that those in the duodenum were recorded about a second later than those in the stomach. Hunger pains developed during the experiment, and these again coincided with a rise of diastolic pressure.

The rapid conduction of the large pressure waves from stomach to duodenum indicates that the pylorus must have been patent during the observation, which is opposed to Hurst's view¹⁵ that gastric pain is caused by the ballooning of the pyloric part of the stomach against a closed pylorus by the peristaltic contraction. Dr. Edmund Spriggs and Mr. O. A. Marxer have very kindly allowed me to quote further evidence in the same direction. Their patient had a gastric ulcer high up on the lesser curvature which was examined radiographically during pain. Six rapid exposures were taken at one second intervals during the progress of a single peristaltic contraction. The latter caused a lateral movement at the site of the ulcer with an alteration in its shape, while during part of the cycle the pylorus was again widely patent.

In applying a theory of visceral pain to pathological states it is necessary to consider in the first place whether in the case of chronic peptic ulcer: (1) pain results from the mere contact of the ulcer with the gastric HCl; or (2) from the movement of the ulcer itself in course of the peristaltic wave; or (3) whether the ulcer itself is specially sensitive to pressure effects. The first suggestion is now so generally discredited that I need only mention the fact that pain may be present with peptic ulcer when there is no free HCl

ably the explanation is that HCl produces primarily increase of tonus.

If the second suggestion were true the pain in peptic ulcer, as Bolton has pointed out, might be expected to differ in its nature and time relation from the pain in other conditions where there is no lesion of the visceral wall; but it is now generally recognised that it may be absolutely impossible to distinguish between the dyspepsia of peptic ulcer and gastric carcinoma and the reflex dyspepsias of

FIG. 8.

A. Eructation. B. More pain. C. Less pain. D. No pain.

FIG. 7.

of the stomach. Further, the results of our experiments are entirely opposed to the suggestions that the HCl of the stomach (Bolton¹¹) or the acrid contents of the stomach (Mackenzie¹² pp. 134, 140), or organic acid (Macleod¹³) directly cause heartburn when they come in contact with the oesophageal mucous membrane. In an experiment on W. W. P., in which oesophageal pain had been produced mechanically, no sensation whatever was felt when a syringe full of his gastric contents containing free HCl was withdrawn and injected directly into the oesophagus. However, pain is produced in some cases by introducing HCl into the stomach, as Palmer¹⁴ has shown. Presum-

ably the explanation is that HCl produces primarily increase of tonus. The third suggestion might be put forward in this form—viz., that peptic ulcer, like other more distant lesions, may produce reflex oesophageal pain; but that in the stomach and duodenum the pain occurs at a lower diastolic tension owing to special sensitivity of the ulcer. Against this view I can bring forward some evidence.¹⁵ In two cases, one of gall-stones and another where gastric and duodenal ulcer had been excluded by operation, abdominal pain was associated with a rise of intragastric pressure; but this was no higher than was the case in our patients suffering at the time from peptic ulcer.

I would support the view that visceral pain is an affair of the whole visceral wall and not of any isolated lesion in it, and that peptic ulcer produces painful effects secondarily by causing reflex increase of tone. Sensation is discontinuous while peristaltic waves are passing, but continuous without them. Further, pain is produced in exactly the same way in any reflex dyspepsia or even when a meal of badly masticated food has been eaten too rapidly. The ulcer may produce these reflex effects because it breaks the continuity of the muscle and in a sense acts like a foreign body.

There is evidence in the literature that raised diastolic pressure, which usually means raised diastolic tension, is the factor on which gastric sensation depends. Thus Carlson¹⁶ (p. 67) stated that a certain degree of constant (or tonic) contraction in the empty stomach appears to give rise to a continuous hunger sensation. The interesting observations of Reynolds and MacClure¹⁷ must also be considered. In 10 out of 12 patients they found, by means of X ray examination, a modification of the gastric movements during pain. The peristalsis might be exaggerated, it might die away altogether, or it might become irregular and then die away altogether, or an incision might be developed. These latter observations show

After a prolonged experiment entailing much pain cutaneous hyperæsthesia was once felt by W. W. P. over the lower part of the sternum, and several times some ten minutes to one hour after the removal of the bag a pain was felt behind at the angle of the left scapula, as if the muscles were stiff, and there was tenderness on palpation. Another subject who kindly volunteered on one occasion felt pain in the back when the bag contained 40 c.cm. Further, we have to record that experiments of this kind may produce unpleasant results subsequently. Thus E. P. P., who never has indigestion, woke up with quite a severe attack on the day following a painful experiment, and W. W. P. has found that his dyspepsia was made worse by the experiments, and even more than two and a half years after the last experiment he still feels a little uncomfortable after breakfast. We may assume that these experiments caused damage to the structures in the wall. Obviously there is no fundamental distinction between pain produced experimentally and the pain of organic visceral disease.

CLINICAL APPLICATIONS.

Payne and I²³ have described an interesting clinical case, which would seem to have a direct bearing on the experiments just described. The patient, W. P., was a man aged 36 with severe gastroparesis who came to out-patients at Guy's complaining of two pains, which he had not noticed before, one at the top of the sternum and the other at the xiphisternum. A radiogram (shown as a sketch in Fig. 3 (E)) had a remarkable appearance, since most of the intrathoracic part of the œsophagus exhibited a constant dilatation, the walls of which were shown up by the trickling down of the barium. There were two constrictions filled with barium, one above the level of the arch of the aorta and the other about where the œsophagus passed through the diaphragm. Comparing this picture with the picture of the air bags in the œsophagus it certainly suggests that in this case the œsophagus produces pain by acting as its own air bag, the air being prevented from escaping by means of the two constrictions. The explanation as to why pain was felt at the top and bottom of the œsophagus rather than in the middle where the dilatation was greatest is probably given by experiments of Boring,²³ who showed that with pressure exerted at different levels in the œsophagus the tendency was to refer the pain above or below, rather than to an intermediate level, and this is decidedly borne out by our own experience.

Owing to the exigency of space in the hospital medical X ray room we were compelled to use a much simpler method than that already described in order to observe the movements in our clinical cases. A finger-stall was tied on to the end of a Ryle's tube and was connected by a T-piece with a syringe and a manometer. The whole system was filled with water and the position of the small bag was determined by X rays which showed up the lead weight at the bottom of the Ryle's tube and the small metal collar inside the Ryle's tube on which the finger-stall was tied. This was marked on the surface of the body and the corresponding level on the manometer tube was determined by means of a straight edge and a spirit level. One of us called out every 5 seconds while the other noted the level of the manometer and the amount of the excursion, and the patient said whether his pain was severe or not at the same time.

The patient W. P. was examined after admission to the hospital, when his œsophageal symptoms had improved, and it was noted that the pain was usually connected with a rise of pressure which was sometimes very great and was due to a peristaltic wave. Close inspection showed that the pain usually increased just when the relaxation was beginning and sometimes the contraction diminished the pain, thus fitting in with the experimental results on ourselves. Between the contractions the pressure was negative, as is usually the case in the intrathoracic part of the œsophagus. We did not carry out observations at the same time as Fig. 3 (E) was obtained, or otherwise the

whole of the intrathoracic œsophagus must have shown a positive diastolic pressure. Observations on my colleague showed that positive diastolic pressures in the œsophagus may be obtained (Fig. 7). They were made at lunch time, when the subject was distinctly hungry. A relatively high diastolic pressure was observed when the bag was 1 cm. above the cardia, and at X a burning pain was felt just before the highest excursion of the manometer was obtained. As the bag was raised the pressure fell steadily; but it was still positive at 14 cm. above the cardia, which was the highest position at which the bag could be retained. However, at this time the œsophagus had become less excitable, since a lower pressure was obtained when it was again lowered into the neighbourhood of the cardia. I will also quote observations on the lower end of the œsophagus in the case of a patient 63 years old who had been treated medically for juxta-pyloric ulcer. On June 10th he complained of continuous pain which fluctuated in intensity and was situated in the mid-line about the lower end of the sternum. The diastolic pressure was found to be uniformly high—about 30 cm.—and the systolic excursions were not very large—about 15 cm. When the second experiment was carried out on June 23rd pain had been absent for some days. The presence of the bag excited the œsophagus to some extent to begin with, but soon the pressure settled down to quite a low level—about 5 cm. At the end of the experiment he swallowed; a very big rise of pressure of about 45 cm. followed, and it is interesting that the systolic pressure was as high as any obtained on the previous occasion, when the patient complained of pain. We carried out a number of similar experiments, and we always found that substernal pain due to dyspepsia was associated with activity of this kind.

As an illustration of the causation of gastric pain I will quote the case of a patient—P. F.—a labourer, aged 62, who had had a gastric ulcer in 1909, for which gastro-jejunostomy was performed. This relieved him of his symptoms for a time. The pain then returned and he was operated on again in 1920, when an ulcer was found on the lesser curvature adherent to the liver. The stomach was opened and the ulcer cauterised without affording him any relief. He vomited sometimes and complained of flatulence. X ray showed that the barium passed immediately through the gastro-jejunostomy opening, while the stomach was often over-distended with air. At first, when the stomach was examined, there was very slight pain, and the pressure was about 10 cm. of water, which is about normal. Then the pain suddenly became very severe, and this was associated with a rise of diastolic pressure while big systolic contractions also appeared. While these observations were in progress the level of the manometer suddenly fell, while the large systolic contractions still continued. At the end of the experiment it was observed by X rays that the bag had passed through the stomach and had taken up its position quite low down in the loop of the jejunum. If the zero is corrected for this fall the diastolic and systolic pressures remain very much the same in the jejunum as in the stomach. The pain was felt all the time in the epigastric angle, which was rather higher than the part that was being investigated, though at other times he noticed pain below the umbilicus. Another patient, J. Ch., aged 42, was a case of duodenal ulcer. He had had severe pain for five years coming on one and a half hours after food and accompanied by headache. X ray showed a small transverse stomach which was emptied in one and a half hours. There was also hyperchlorhydria. One of many observations on the duodenum is shown in Fig. 8. But exactly similar results were also obtained in the stomach. He was able to grade his pain, and it will be noticed that as this became more severe the diastolic pressure rose and an eructation often followed, after which the diastolic pressure always fell, to rise again in a minute or so's time. These periodic rises of diastolic pressure in stomach and duodenum with resulting symptoms were always obtained when the patient was fasting; but after a

meal the pressure was lower, while the record remained flat and the patient was quite comfortable with no sensations.

We carried out further observations on this patient to find out the relation between the contractions of the stomach and the duodenum by means of two bags each attached to a manometer, while the excursions of both manometers were recorded on a kymograph. It was found that the systolic rises of pressure in the stomach and duodenum were similar to one another; but that those in the duodenum were recorded about a second later than those in the stomach. Hunger pains developed during the experiment, and these again coincided with a rise of diastolic pressure.

The rapid conduction of the large pressure waves from stomach to duodenum indicates that the pylorus must have been patent during the observation, which is opposed to Hurst's view¹⁵ that gastric pain is caused by the ballooning of the pyloric part of the stomach against a closed pylorus by the peristaltic contraction. Dr. Edmund Spriggs and Mr. O. A. Marxer have very kindly allowed me to quote further evidence in the same direction. Their patient had a gastric ulcer high up on the lesser curvature which was examined radiographically during pain. Six rapid exposures were taken at one second intervals during the progress of a single peristaltic contraction. The latter caused a lateral movement at the site of the ulcer with an alteration in its shape, while during part of the cycle the pylorus was again widely patent.

In applying a theory of visceral pain to pathological states it is necessary to consider in the first place whether in the case of chronic peptic ulcer: (1) pain results from the mere contact of the ulcer with the gastric HCl; or (2) from the movement of the ulcer itself in course of the peristaltic wave; or (3) whether the ulcer itself is specially sensitive to pressure effects. The first suggestion is now so generally discredited that I need only mention the fact that pain may be present with peptic ulcer when there is no free HCl

ably the explanation is that HCl produces primarily increase of tonus.

If the second suggestion were true the pain in peptic ulcer, as Bolton has pointed out, might be expected to differ in its nature and time relation from the pain in other conditions where there is no lesion of the visceral wall; but it is now generally recognised that it may be absolutely impossible to distinguish between the dyspepsia of peptic ulcer and gastric carcinoma and the reflex dyspepsias of

FIG. 8.

FIG. 7.

of the stomach. Further, the results of our experiments are entirely opposed to the suggestions that the HCl of the stomach (Bolton¹⁶) or the acrid contents of the stomach (Mackenzie,¹⁷ pp. 134, 140), or organic acids (Macleod¹⁸) directly cause heartburn when they come in contact with the oesophageal mucous membrane. In an experiment on W. W. P., in which oesophageal pain had been produced mechanically, no sensation whatever was felt when a syringe full of his gastric contents containing free HCl was withdrawn and injected directly into the oesophagus. However, pain is produced in some cases by introducing HCl into the stomach, as Palmer¹⁹ has shown. Presum-

gall-stones, cholecystitis, appendicitis, and even pancreatitis on the symptomatology alone. Surely the mechanism of the pain must be the same in all these. I should like to mention briefly a case imitating duodenal ulcer. A man, aged 49, had hunger pains, and the small transverse stomach regarded as typical of duodenal ulcer, but no occult blood in the stools. An experienced surgeon said that he was convinced that a duodenal ulcer would be found in spite of negative X ray evidence, but operation disclosed chronic pancreatitis. Furthermore, Payne and I have brought forward evidence that the pain of peptic ulcer is often produced in the oesophagus—i.e., somewhere away from where the lesion is situated.

The third suggestion might be put forward in this form—viz., that peptic ulcer, like other more distant lesions, may produce reflex oesophageal pain; but that in the stomach and duodenum the pain occurs at a lower diastolic tension owing to special sensitivity of the ulcer. Against this view I can bring forward some evidence.²² In two cases, one of gall-stones and another where gastric and duodenal ulcer had been excluded by operation, abdominal pain was associated with a rise of intragastric pressure; but this was no higher than was the case in our patients suffering at the time from peptic ulcer.

I would support the view that visceral pain is an affair of the whole visceral wall and not of any isolated lesion in it, and that peptic ulcer produces painful effects secondarily by causing reflex increase of tone. Sensation is discontinuous while peristaltic waves are passing, but continuous without them. Further, pain is produced in exactly the same way in any reflex dyspepsia or even when a meal of badly masticated food has been eaten too rapidly. The ulcer may produce these reflex effects because it breaks the continuity of the muscle and in a sense acts like a foreign body.

There is evidence in the literature that raised diastolic pressure, which usually means raised diastolic tension, is the factor on which gastric sensation depends. Thus Carlson²³ (p. 67) stated that a certain degree of constant (or tonic) contraction in the empty stomach appears to give rise to a continuous hunger sensation. The interesting observations of Reynolds and MacClure²⁴ must also be considered. In 10 out of 12 patients they found, by means of X ray examination, a modification of the gastric movements during pain. The peristalsis might be exaggerated, it might die away altogether, or it might become irregular and then die away altogether, or an incisure might be developed. These latter observations show

that the pain had nothing to do with the peristalsis by itself, but it can be explained on our theory as due to increased tonus developing. The same absence of peristalsis was noticed in some of our more painful oesophageal experiments already described. But though continuous, visceral sensation may result from tonus without contractions, I would emphasise the fact that in our clinical cases increased tone and increased peristalsis were usually found together.

During the past ten years or so several papers on the subject of gastric pain have been published by American observers with very conflicting results. In many cases the relation of pain to gastric movement was clearly demonstrated; but in others no such relation was established, and W. L. Palmer,²⁵ in summing up his conclusions, says that "the pain producing mechanism is not usually dependent on gastric or duodenal tone or motility of pylorospasm; but under certain conditions normal gastric peristalsis may constitute the adequate stimulus." The following criticisms may be brought against all this work: (1) An air bag was usually employed, located in the fundus. The advantage of our small water bag is that it can be readily passed into the pyloric part of the stomach and beyond. We found that in the elongated stomach when the walls sagged together no movements at all were transmitted from the pyloric part of the stomach to the fundus. (2) The air bag was apparently blown up tight and no actual figures are given for the intragastric pressure. Under these conditions the air bag would be more liable to act as a foreign body than our small water bag. This is illustrated by the radiograms of Rogers and Hardt.²⁶ (3) Often no account is taken of the place where pain was felt, but in these experiments it is essential to differentiate between oesophageal and gastric pain. (4) The mere introduction of 200 c.cm. or more of fluid into the stomach by increasing the radius will increase the tension of the wall and so cause pain, even though there is no increase of pressure recorded, and the discrepancy in some of Palmer's observations may be due to this. Taking all these things into consideration it is not very surprising that in many cases the relation of pain to the mechanical condition of the various organs was often not established.

However, on examining those published cases where pain was found to be related to gastric movement I find that they are divisible into two groups. In one the peristaltic wave has a clearly defined pointed summit, and in this case the sensation is recorded during the relaxation. The earliest example of this kind was published by Carlson²⁷ (Fig. 1), and he draws the conclusion that "gastric contractions preceded the ulcer sensation just as they preceded the hunger pang." He has further stated that "when the stomach contraction is of moderate severity and the hunger sensation of moderate intensity the hunger sensation gradually ceases at the height of the contraction." A similar observation has been published by Palmer²⁵ (Fig. 6) and by L. L. J. Hardt²⁸ (Fig. 3 (A)). It is also interesting that W. H. Ogilvie²⁹ observed that a patient whose gall-bladder was intubated complained of pain as the pressure fell at the end of a contraction. These observations surely provide the direct clinical proof of the correctness of our theory that a successful peristaltic contraction relieves visceral pain which appears again when the condition of tension on the nerve-endings becomes re-established during peristaltic relaxation. It is true that Carlson²⁷ and Hardt²⁸ have suggested that this result may be explained by the pain being produced by contraction of the pyloric end of the stomach, which occurs some seconds after the contraction of the fundus in which the bag is situated. But this suggestion does not give a true picture of events in the stomach. We have found by simultaneous X ray and manometric observation of one case that the peak of the pressure wave corresponds with the deepest indentation of the greater curvature, while the peristaltic wave sweeps round towards the pylorus. The pressure changes are communicated simultaneously through the stomach, and in the case of J. Ch.

very rapidly to the duodenum. Thus we may conclude that the end of the peristaltic wave recorded in the fundus is simultaneous with the end of the wave produced in the pyloric part of the stomach. But this is a point that Dr. L. T. Ride and myself are further investigating by two small similar bags in different parts of the stomach. The radiograms of the bags in situ by Rogers and Hardt²⁶ suggest that the stomach acts as a whole as far as pressure is concerned, since the bag which occupies the greater part of the stomach is clearly being compressed above and below simultaneously.

Again, a graphic record has been published by Palmer²⁵ (Fig. 7), in which the peristaltic wave has a flat top of some seconds' duration, and in this case the pain coincides with the contraction. It is reasonable at present, I think, to regard this flat-topped wave as being due to a sustained peristaltic contraction which is held up in its course, possibly owing to pylorospasm, so that a condition of painful strain is set up similar to that occurring with the incompressible bag in the oesophagus.

At the end of the previous section we stated that on theoretical grounds the very beginning of a peristaltic wave might be painful. We have some evidence of this from our clinical investigations. For example, W. W. P. (Fig. 7) noticed pain before the highest excursion of the manometer. It is clear that further work on this point is required.

The experiments of A. W. Mayer have been dealt with elsewhere,¹⁸ but it is to be noted that the addition of barium chloride to the peritoneal cavity, which he found to be a cause of pain in certain animals, produces exactly that condition of high tone and held-up peristalsis that we have already shown to be the cause of visceral pain. Further, Mackenzie's¹¹ observation that pain was associated with the contraction of the bowel into a thick fleshy rod and Ryle's³⁰ observation on the pain and tenderness of a spastic colon may be explained in the same way.

An Address

ON

SACRO-ILIAC PAIN

Opening Discussion at a Meeting of the Medical Society of London on Dec. 10th

By WILFRED HARRIS, M.D. CAMB.,

F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ST. MARY'S HOSPITAL, AND TO THE HOSPITAL FOR NERVOUS DISEASES, MAIDA VALE.

DURING the last ten years increasing attention has been paid to the slighter forms of sacro-iliac disease, both in this country and in America. Although Fleming in this country and Bertherand in Belgium had described dislocation of this joint as long ago as the middle of the nineteenth century, it was not until Goldthwait of Boston, in 1905, forced the subject upon the notice of the profession, that relaxations and subluxations of the sacro-iliac joint became generally recognised as a source of the low back pain and chronic sciatica met with chiefly in women, following slight injuries, childbirth, postural relaxation under an anæsthetic, or similar muscular and ligamental strains, such as may be met with in football, wrestling, and in the lifting strains of industrial occupations. A not uncommon cause of the post-operative backache, usually met with in women, is due to the prolonged relaxation of the back muscles during an anæsthetic while lying on a flat table, when the surgeon has omitted to place a cushion under the small of the back.

ANATOMICAL FEATURES.

The sacro-iliac joint is what is known as a diarthrodial joint, is lined by cartilage, and has a synovial cavity, best marked in the female at the time of childbirth. The facets of articulation between the

ilium and sacrum are somewhat auricular in shape, and in the erect position the weight of the body transmitted through the lumbar vertebrae to the sacrum produces a shearing strain in the two sacro-iliac joints, tending to force the sacrum downwards between the two ilia. The joints are supported mainly by the anterior and posterior sacro-iliac ligaments, of which the posterior is by far the stronger and most important, so strong indeed is it that it has been found impossible to rupture it experimentally, the bony surfaces tearing away first. In addition, the glutei and erector spinae, by their tonic contraction acting on the sacrum and ilium, help to support the joint. In the male there is usually sufficient joint locking to prevent any but the smallest movement, but in the female pelvis the bony surfaces are smoother and the joint capable of greater range of movement, especially during parturition. It is therefore in the female more particularly that sacro-iliac strains and subluxations are liable to occur, owing to the two factors of greater mobility of the joint and weaker muscles.

TYPES OF SACRO-ILIAC LESIONS.

As already said, the ligaments are practically impossible to rupture, and therefore we shall not expect ever to find a true downward dislocation of the sacrum, but a torsion or partial rotation of the joint, in which the sacrum may tilt either forwards or backwards upon its articulation with the ilium. The commoner form is that in which the sacrum is rotated backwards, producing "flat back," with more or less obliteration of the normal lumbar curve, such as may occur after a prolonged anaesthetic. In the relaxation form of subluxation, produced by prolonged standing, especially in heavy women with pendulous abdomens, the sacrum may be tilted forwards, causing an exaggerated lordosis, with symptoms of dull chronic feeling of fatigue, with pains in the lower back, radiating up the spine. In this type there is no hamstring spasm present, though in the flat back variety spasm of the hamstring muscles becomes so severe that extension of the leg upon the thigh flexed on the abdomen becomes impossible without considerable pain referred to the affected joint.

Diagnosis of these subluxations by X rays appears to be impossible except in rare cases, and this has been cited as a reason for doubting the possibility of their occurrence in any frequency. Whenever possible to obtain, stereoscopic X ray pictures of the pelvis should be insisted on, and lateral as well as antero-posterior views.

Clinical experience of these low back pains, fortified by their speedy or even sudden and dramatic relief by measures calculated to reduce such subluxations, should convince us of their importance in the symptomatology of chronic pains in the back, which have been in the past, and indeed still are diagnosed variously as lumbago, muscular rheumatism, and chronic sciatica.

These strains of the joint may be divided into three classes: (a) sudden or acute, (b) subacute, (c) chronic. An example of the sudden form will be that resulting from a violent blow, as in a motor accident, or from a fall.

Some weeks ago I saw a lady who was supposed to be suffering from chronic sciatica. She was in constant pain and unable to get about much, limping on the right leg and complaining of pain down the back of the leg, and also around the hip into the groin. She gave a history of sudden onset of the pain following an accident in her car, a small station, which was struck from behind by a heavy lorry, the blow jarring her right buttock and being followed instantly by local pain and difficulty in walking. There was local tenderness on pressure below the posterior superior iliac spine on the right side, with pain on compression of the iliac crests, while the Achilles jerk was normal, and her lumbar curve was somewhat rigid and appeared to have lost that easy wave of the normal curve. I came to the conclusion that it was a case of true sacro-iliac subluxation due to direct injury, and handed her over to Mr. E. F. Cyril for manipulative treatment, with excellent results.

The acute form of sacro-iliac lesion is liable to be produced by a heavy lifting strain when stooping, when the sensation may be felt as of something

snapping, followed by a difficulty in holding the body erect, with the appearance of sharp pain in the lower lumbar region. This pain may disappear after a rest, reappearing and becoming worse next day, causing practically complete disablement, the pain being at first localised in the region of the joint, and later spreading through the whole lumbar region, buttock, and leg on the affected side. Mr. P. J. Verrall has well described the patient's sensation as one of extreme instability, and of "falling to pieces."

NERVE RELATIONSHIPS.

All the nerves in the neighbourhood of the joint supply it with articular branches, the nerve-supply being thus derived from the lumbo-sacral cord, the first and second sacral nerves, the obturator, and the superior gluteal. The lumbo-sacral cord, which it will be remembered is made up of a large branch from the fourth lumbar anterior division to join the fifth lumbar nerve, passes downwards and outwards in front of the lower third of the sacro-iliac joint on its way to join the first sacral nerve and the sacral plexus. Since this lumbo-sacral cord is an anterior relation of the joint it is no matter of surprise that in disease of this joint neuralgic pain may be referred along the distribution of the sciatic nerve down the leg to the ankle and foot, while in other cases, through the obturator nerve, pain may be complained of in the region of the hip-joint and groin and even in the knee. Tenderness on pressure over the affected sacro-iliac joint is almost constant, and compression of the iliac crests or pressure on the pubes will cause pain referred to the affected joint. Pain will be aggravated by walking, by sitting on the affected side, by standing, or by lying flat on the back, while bending becomes difficult and lifting a weight almost impossible. The posture may be diagnostic, the lumbar curve either flattened or with an exaggerated lordosis, and the spine tilted to one side, usually away from the affected joint. In walking upstairs much disinclination is shown to throw the weight on the leg on the damaged side, more so than in osteo-arthritis of the hip-joint, which is one of the conditions which is liable to be confused with sacro-iliac joint disease. Goldthwait's symptom is pain referred to the joint or to the leg of the affected side when the leg is extended on the flexed thigh. When this test causes pain referred to the damaged sacro-iliac joint, it is probably caused by spasm of the hamstrings through their attachment to the ischial tuberosity pulling on the ilium and tending to force rotation of the ilium on the sacrum. This method may indeed be used to reduce the backward rotation of the sacrum, causing "flat back," but probably the better and less painful method is to exert pressure with one hand on the sacrum, while the other pulls the ilium backwards by gripping the anterior superior spine. When lordosis is exaggerated by a forward rotation of the sacrum, any forced hyperextension of the leg can only do harm, and rest in bed in the supine position is probably advisable. The treatment, however, of sacro-iliac subluxations, whether by manipulations under an anaesthetic or without, by strapping or other supports, or by the operation of permanently fixing the joint by arthrodesis, is beyond the scope of my opening remarks, and will no doubt be adequately dealt with by the surgeons.

DIFFERENTIAL DIAGNOSIS.

The differential diagnosis from sciatica, spinal cord disease, arthritis of the hip, lumbago, and sacral fibrositis are, however, of pressing importance from the medical point of view. It is the American surgeons particularly who have during the last ten years investigated and written upon the subject of sacro-iliac sprains, and have helped to rescue many sufferers with chronic pain in the back from the manipulative movements. Goldthwait,¹ who in 1905 based his paper on 500 cases, went so far as to say

¹ Goldthwait, J. E.: Boston Med. and Surg. Jour., 1905, clii, 280.

that most cases of chronic sciatica are due to sacro-iliac subluxations.

Hoyt Cox,² of Chicago, also wrote last year: "Chronic sciatica is, of course, only a symptom, and is usually due to pressure or irritation of the sciatic nerve from some external source. However, it may be due to focal infection in rare cases." Without going so far as to accept this sweeping generalisation that chronic sciatica is usually a surgical disease, we should always be on our guard not to overlook injury or muscular strain damaging the sacro-iliac joint and simulating sciatica through its pain reference along the lumbo-sacral cord. This error we shall be less liable to fall into if in our routine examination of the patient we always test for tenderness over the joint by pressure on and below the posterior iliac spine, and also try the effect of compression of the iliac crests. When neither of these tests causes pain referred to the joint, we shall be fairly safe in excluding sacro-iliac sprain.

Again, Lasègue's sign in sciatica is the production of pain referred along the nerve when the leg is extended on the flexed hip, a sign already claimed by Goldthwait as due to sacro-iliac subluxation. There can be no question that this sign is commonly present in many acute sciaticas, and may still be present when the acute stage has passed into the chronic stage, so we shall probably err on the side of safety if we do not accept the whole of Goldthwait's dictum, but limit the value of his sign of sacro-iliac sprain to those cases in which the pain is referred to the actual joint region, whether or no there is also pain referred down the leg.

Chronic Sciatica.

A valuable sign in subacute and chronic sciatica is loss of the Achilles jerk, indicating that the neuritic process has passed inwards from the nerve sheath and is actually involving the nerve bundles. This is probably the earliest sign indicating actual damage to the nerve-fibres, invariably preceding anaesthesia of the foot or muscular wasting, and usually to be found before the patient complains of coldness, numbness, or blueness of the foot. The posture in sciatica may give rise in certain cases to a suspicion of sacro-iliac sprain or subluxation. Though there may be tilting of the spine to the same or to the opposite side, there will be none of the extreme disability described by Verrall as "falling to pieces," with the extreme disinclination to throw the weight on the hip of the affected side in going upstairs. In some cases of chronic sciatica the tilting to the same side is so great that the patient appears drawn down on that side, limping with knee bent, and a homolateral scoliosis. In that type the Achilles jerk may be lost, and the site of the perineuritis is at the sciatic notch, and affects the upper two or three inches of the nerve in this region. This type is often curable by massive saline injections into the nerve.

Another rarer type, in which contra-lateral scoliosis is a marked feature, is more chronic even than the last as a rule, there is no loss of the Achilles jerk, no muscular wasting or numbness of the leg, but pain is complained of in the sciatic distribution, and there is often tenderness on deep pressure over the region of the fourth lumbar transverse process on the affected side. The spine is tilted towards the opposite side, sometimes as much as five inches when a plumb line is dropped from the seventh cervical spine, and pain down the affected leg is produced by forcibly pulling the shoulders towards the affected side when counter pressure is kept up by the knee against the patient's hip. The tilting is not due to the pelvis being thrown to one side with the heel raised, as with both heels on the ground the crests of the ilia are perfectly level. The cause of this type of sciatica appears to be some inflammatory lesion, such as fibrositis, irritating one or more nerve-roots close to the intervertebral foramina. The tilting of the spine is a protective scoliosis, so as to open out as far as possible the intervertebral foramina on the affected side. I have seen

one such case of left-sided sciatica, with lateral scoliosis towards the right, which was cured instantaneously by an injection of alcohol deeply into the tender area behind and below the left fourth lumbar transverse process. Saline injections into the nerve I have found of no value in this type of sciatica, but they usually recover after prolonged rest in bed, aided by massage, radiant heat, and ionisation. It is clear, therefore, that these cases are to be distinguished from sacro-iliac sprains, and have nothing in common with them.

Traumatic Sciatica.

Chronic sciatica may be the result of a fall on the buttock, actual contusion of the nerve probably resulting from the injury. I have seen such a case recover in less than a week after massive saline injection into the nerve at the notch, though the pain and disability had already lasted for many weeks following a fall in the hunting field. Similarly, another case of a coal-miner, when walking along an underground gallery, in order to save himself from being run down by a trolley load of coal, had to throw himself suddenly sideways, falling on a mass of loose debris. Immediately he felt severe pain in the buttock and was unable to rise, the pain later spreading downwards like a sciatica. After three months of constant pain and disability he was sent up to St. Mary's Hospital where I injected the sciatic nerve at the notch with 80 c.cm. of saline. His cure was most dramatic and almost instantaneous. This was many years ago, before I knew anything of sacro-iliac sprain, and if I saw such a case now I should carefully examine him from this point of view, but the result of his treatment is proof that his sciatic nerve and not his sacro-iliac joint was at fault, the nerve probably being irritated by fibrositic scar at the notch, resulting from a ruptured muscle bundle and hæmorrhage.

It was from Mr. Blundell Bankart that I first learnt several years ago how easy it may be to mistake sacro-iliac sprain for a chronic sciatica. I had been treating a lady for some time with rest in bed, and had given her two saline injections into the nerve without benefit, when he was called in, made the diagnosis of sacro-iliac subluxation, and manipulated the pelvis under an anaesthetic, getting the "click" that is said to occur as the joint slips into place, with a resulting immediate cure. The meaning of this click has been variously explained, some authors saying that it is produced by rubbing of thickened fibro-cartilage in the joint, as the result of a chronic inflammatory process.

Sepsis.

Septic infection is an important cause of neuro-fibrositis and joint inflammations, and its influence was well shown in the case of a young married woman of 31, who had had periodic lumbar pain for five years following childbirth. For four months before I saw her she had been complaining of sciatic pain shooting down to the left ankle, with pricking pains in the calf. The Achilles jerk was normal, and there was general tenderness in the buttock, the pain appearing to come from the bottom of the spine. I was suspicious of sacro-iliac relaxation, owing to the history of pain following childbirth, but could get no evidence confirmatory of this on testing. The pain was aggravated by coughing or sneezing and by extension of the knee on the flexed hip, and she was unable to wear a high-heeled shoe, as it increased the pain. No treatment appeared to be of any avail, and the pain continued for some months until a septic molar tooth was extracted, when all the symptoms cleared up in a few days.

OTHER CAUSES OF PAIN IN THE BACK AND LEGS.

This is not the place to enumerate all the various causes of sciatica, which are legion, but in the differential diagnosis of sacro-iliac pain it is important to exclude diabetes. Tubercle may attack the sacro-iliac joint, with the formation later of a cold abscess.

² Cox, H. H.: *Surg., Gyn., and Obst.*, 1927, xlv., 637.

Tubercle of the sacrum or of the lumbar vertebrae may be recognised by radiography, though new growths in the rectum or in the pelvis, or of the lumbar cord or cauda equina may show nothing on radioscopic examination without special arrangements. An opaque enema may be of the greatest assistance in the radioscopic examination of the rectum and colon, while tumours within the spinal theca damaging the nerves or cord may be indicated by X rays after an injection of lipiodol by cistern puncture, the heavy opaque oil falling down through the cerebro-spinal fluid to the site of the tumour, where it is held up and prevented from reaching the conical termination of the thecal cavity at the level of the first sacral body.

Clinically, such tumour should produce symptoms of muscular wasting and anaesthesia, according to the roots involved, with appropriate loss of reflexes, thus the knee jerks will not be affected by lesions below the fourth lumbar root, the Achilles jerk being served by the first sacral.

Sacralisation.

Sacralisation, or semi-sacralisation of the fifth lumbar vertebra, is another cause of low back pain, with or without pain referred along the sciatic nerve. This process of sacralisation consists usually of a much enlarged transverse process on one side which may articulate either with the top of the sacrum or with the iliac crest. All degrees are met with up to total bony ankylosis of the fifth lumbar vertebra with the sacrum. Owing to the fact that the fifth lumbar nerve is the largest of the lumbar nerves, whilst its foramen between the fifth lumbar vertebra and the sacrum is the smallest of the lumbar foramina, congestion of the venous plexus around the nerve or a rheumatic or infective fibrositis may very easily lead to compression of the nerve, and thus a referred sciatica is set up, and even symptoms of definite neuritis, with wasting of the leg muscles below the knee. Sacralisation is only rarely found in Europeans, and is a retrograde developmental anomaly, being commonly found in non-European races, and almost invariably in the anthropoid apes.

Osteo-Arthritis.

Osteo-arthritis of the hip-joint is a fertile cause of error in the diagnosis of sciatica, and may similarly be mistaken for sacro-iliac sprain. The pain is usually around the hip into the groin, and even into the knee, while rarely the only pain complained of may be below the knee down to the ankle. On examination, there will usually be found limitation of rotation and of abduction of the hip, with pain on movement, the pelvis tending to move as a whole with the thigh movement. X rays will show mushrooming of the head of the femur, loss of the articular cartilage, and disappearance of the articular space, with lipping from osteophytes at the edges of the acetabulum. Many of these cases are, however, complicated by the presence of true sciatica in addition. Since the nerve passes very close to the back of the joint, it is not surprising that the chronic inflammatory process giving rise to osteo-arthritis of the hip may also invade the sheath of the sciatic nerve.

X rays have comparatively recently demonstrated a number of cases of *osteitis deformans*, or Paget's disease of the bones, invading the ischium and other bones of the pelvis and producing symptoms that are easily mistaken for chronic sciatica.

Just as sacro-iliac enthusiasts in America have asserted that nearly all chronic sciaticas are really sacro-iliac sprains or subluxations, so also have similar assertions been made by spa physicians that all sciaticas are really secondary to osteo-arthritis of the hip. Steering a middle course between these all-embracing claims, we may yet learn a good deal from them, and will hesitate to diagnose true chronic sciatica without a careful X ray examination to exclude arthritis of the hip or other bony disease, and at the same time we must not forget to examine for evidence of exostotic disease.

TREATMENT AND PREVENTION OF NON-OBSTRUCTIVE SUPPRESSION OF URINE.

By A. A. OSMAN, D.S.C., M.R.C.P. LOND.,*

PHYSICIAN TO QUEEN MARY'S HOSPITAL, STRATFORD, AND SENIOR MEDICAL ASSISTANT, GUY'S HOSPITAL.

SUPPRESSION of urine is at all times a serious symptom and one which calls for prompt treatment. It is, moreover, a condition which is liable to occur at any time and is always to some extent an emergency. Measures for relief, to be successful, must be readily applicable, and must not require elaborate laboratory investigations. The procedure described here has been evolved during the course of a prolonged research on the treatment of nephritis and allied conditions with alkalies. Twenty-four cases of severe, partial, and complete suppression were met with, and as their suppression of urine always reacted satisfactorily to the treatment it was considered desirable to publish them separately in the hope that the measures might prove of value to others. No example of the prolonged complete anuria lasting from 10 to 14 days, described in text-books, has so far been met with, and until such cases have been successfully treated the method cannot be said to be infallible. Anuria of this extreme degree is so rarely encountered in the experience of one individual, however, that it seemed unwise to defer publication of what may prove a valuable therapeutic measure in milder cases.

Total or partial suppression of urine occurs in the following conditions:—

1. Acute nephritis.
2. Acute exacerbations occurring in the course of chronic nephritis, which are usually caused by (a) superimposed infection, (b) over-exertion, (c) the administration of general anaesthetics such as chloroform and ether, and the therapeutic use of certain heavy metals and metallic compounds such as lead, mercury, gold (sancrysine), and arsenic (salvarsan).
3. Heart failure.
4. Fevers and inflammatory conditions.
5. Acute poisoning by phosphorus, turpentine, and the above-named metals.
6. Collapse after severe operations or the passage of a catheter.
7. Cholera and blackwater fever.

Total suppression may be present for 10 to 14 days before death in rare instances, but a fatal issue from respiratory or cardiac failure quite often occurs before this. Drowsiness, headache, vomiting, contracted pupils, and a subnormal temperature are usually present. Deep coma is comparatively rare, consciousness often being retained to the end. Convulsions are likewise rare or occur just before death. Irregularity of the pulse is a grave sign. Anuria, even when complete, is not necessarily fatal, whilst recovery from partial suppression is not uncommon. Nevertheless this symptom is always cause for grave anxiety as, when it does not itself lead directly to death from uraemia, the accumulated "toxic" substances act adversely on other organs and tissues which may or may not have been previously damaged. Anuria may therefore be a primary or secondary cause of death.

The treatment usually recommended consists of measures designed to promote elimination of waste products through the skin and bowels by means of hot baths, diaphoretics, and purges, whilst counter-irritation is applied to the kidneys in the form of dry cupping, hot applications, and warm colonic douches. Most writers point out that diuretics act best, if at all, after the secretion has once started. These proved not invariably successful. We believe that our method exerts a direct action on the kidney and initiates and maintains the secretion of urine. The underlying

* Working with the aid of a grant from the Medical Research Council.

theory, and the evidence upon which it is based, have been discussed at some length elsewhere.¹

The cases of partial suppression described include only those in which the urinary output had fallen to six ounces or less in the 24 hours. No cases have been included in which the urinary output was on the increase when treatment was commenced. The distinction is important. The method consists simply in giving by mouth (or per rectum when coma is present) a mixture of alkaline salts in increasing amounts until diuresis is obtained. It has been found that in cases of suppression and of nephritis with oliguria there is an associated acidosis—acidosis being here defined as a condition in which the plasma bicarbonate is reduced (van Slyke). I do not propose to discuss now the relation of the acidosis to renal function—i.e., whether it is caused by or is the cause of the latter, but the plasma bicarbonate is decreased in many conditions in which there is no obvious impairment of renal function, and frequently, if not always, when there is suppression of urine. The plasma bicarbonate was markedly reduced in each of the nine cases in which it was estimated in this series. When this is the case alkalies can be given in comparatively large amounts without danger, and, as the present series of cases suggests, in amounts sufficient to produce diuresis. If further investigation confirms the findings recorded here, it may be said that the plasma bicarbonate is always reduced with suppression of urine, and that it will be safe to give alkalies in amounts sufficient to cause diuresis without a preliminary investigation of the bicarbonate content of the blood, as secretion of urine seems generally to begin when the bicarbonate has reached a normal level. Until this level is exceeded little danger is likely to ensue. The practice of giving alkalies in large amounts when the plasma bicarbonate is not known to be decreased cannot be too strongly condemned, as symptoms of alkalosis and tetany are likely to occur.

Procedure for Treatment.

A mixture containing grs. 30 each of potassium citrate and sodium bicarbonate, with some suitable flavouring agent such as syr. aurantii, minims 40, in an ounce of water, is given by mouth at hourly or two-hourly intervals until secretion begins or until it begins to increase. At this point the previously acid urine is usually definitely alkaline. In cases of coma a 3 per cent. solution of the mixture is given per rectum, or a drachm to the pint intravenously, and repeated until either diuresis is established or consciousness is regained, when oral administration is to be preferred. A light diet can be given throughout when desired, and no extra fluid need be given, but the minimum should be not less than three pints a day. The total quantity of fluid intake should be kept reasonably constant from day to day. The number of doses and the total amount of alkali required to start diuresis of course varies in each case, but it is absolutely essential that alkalies should be given continuously until diuresis begins. When the urinary output has reached 10 to 15 oz., and is seen to be still increasing, the alkalies must be reduced in amount, but must not be withdrawn. The total quantity of alkali given in the 24 hours may be reduced by one-third, but if this is followed by a decrease in urinary output the former dose must be resumed immediately. By thus carefully manipulating the dose it is usually possible to maintain a satisfactory diuresis. Complete withdrawal of alkali at the point at which secretion begins is sometimes followed by an anuria, and a second attempt to overcome this by means of alkalies generally demands a much larger dose than before, and this is often dangerous and frequently unsuccessful.

The essential points in the procedure are to give alkalies in increasing amounts rapidly until diuresis commences, then to reduce the dose sufficiently to maintain the flow, but not to the extent of causing a secondary decrease in the secretion. The patient requires unceasing attention and should on no account be left without expert supervision. The chief danger to be feared from overdosage is tetany, but this has

not yet occurred in a case of suppression, probably because diuresis begins and the dose is reduced just before the tetany point—in quantity of plasma bicarbonate—is reached. Tetany produced by overdosage with alkalies is easily overcome by a slight reduction of the dose and by the intramuscular injection of one grain of calcium chloride in 40 minims of distilled water. The injection may be repeated two hours later if necessary. By far the greatest danger in tetany is complete withdrawal of alkalies. Chvostek's sign is generally present, and is an early and valuable warning of the approach of tetany due to overdosage with alkalies.

The after-treatment consists in giving a dose of alkali sufficient to keep the urine definitely alkaline to litmus until the exciting cause of the suppression is overcome or removed.

CASE 1. Albuminuria of pregnancy in labour, second pregnancy.—The patient was a married woman aged 26. She had extreme cedema of legs, thighs, and face, and albuminuria was first noticed on Nov. 7th. She did not attend again until she was admitted in labour on Dec. 12th. On admission at 3 P.M. 2 oz. of urine were obtained by catheterisation, and contained much albumin. Labour commenced at 5 A.M. on Dec. 13th. At 2 P.M. there was no urine; the plasma bicarbonate was 0.0246, and the blood-urea 45 mg. per cent. She was given grs. 60 of alkalies two-hourly, but no urine could be obtained by catheter. At 1 P.M. on Dec. 14th the plasma bicarbonate was 0.0326, and the blood-urea 65 mg. per cent. The dose of alkalies was decreased to grs. 60 six-hourly. At 4 P.M. on Dec. 14th diuresis began. The urine had a hydrogen-ion concentration of 6 and contained 6 parts per 1000 of albumin. A full-term child was born at 7 P.M. on Dec. 14th, three hours after the diuresis had begun.

CASE 2A. Parenchymatous nephritis.—The case was that of a child of 3. There was a 15 months' history of general anasarca, with marked ascites, and the child had passed very little urine for three days before admission. He then passed 1 oz. a day for the next two days. The urine was very acid, loaded with albumin and casts, but contained no blood. He was given grs. 600 of alkali in 48 hours and the urine increased to 14 oz. and became alkaline to litmus. After further grs. 480, the volume increased to 70 oz. He was discharged with no cedema and with his urine free from albumin and casts.

(b) He was readmitted one year later with identical symptoms, having passed scarcely any urine for two days. In the first 24 hours after admission he passed 3 oz. of very acid urine, loaded with albumin and many casts, but no blood. After grs. 560 of alkali, given during the next 24 hours, he passed 8 oz. After further grs. 480 the output increased to 22 oz. The dose was maintained at grs. 480 per diem, and the volume of urine gradually increased to 40 oz. a day. He was discharged without cedema and free from albumin and casts.

CASE 3. Chronic pyelonephritis.—The patient was a girl of 16. She had had puffiness of the eyes and headaches for four years. On admission she was unconscious and there was some twitching of the extremities. The urine was acid, contained albumin, a little blood, and many coliform bacilli. The face and legs were cedematous. The urinary volume averaged 20 oz. for some days and then decreased and finally none at all was passed for three days. At this point the plasma bicarbonate was 0.026 mg. per cent., and the blood-urea was five times normal. She was given grs. 360 of alkali by the mouth, and this was followed by secretion of urine and return of consciousness. Thereafter an adequate diuresis was maintained on a daily dose of grs. 200 and all the symptoms cleared up. Eighteen months later she was still attending the out-patient department for observation.

CASE 4. Sanocrysin poisoning.—This was a case of infective endocarditis in a girl aged 17½, in which subsidence of the temperature and reduction in the size of the spleen had followed a small dose of sanocrysin on several occasions. Three days after a somewhat larger dose than usual the urine rapidly decreased in amount and contained albumin. For three days there was complete anuria with partial coma and uræmic twitchings of the extremities. At this point the plasma bicarbonate was 0.022 molar, and the blood-urea was between four and five times the normal. She was already having grs. 110 of alkali a day and this was increased to grs. 60 hourly. At the end of 24 hours, when she had had grs. 1140, she had passed 20 oz. of urine. The dose was then reduced to grs. 480 a day and the secretion of urine continued in adequate amounts. She became fully conscious and all signs of uræmia disappeared. Later the dose was still further

reduced and she was sent home with her renal condition recovered. I am indebted to Dr. G. Marshall for permission to publish this case.

CASE 5. Chronic parenchymatous nephritis.—The patient was a boy of 4. There was a three months' history of generalised oedema and ascites and he had been passing very little urine for some days. He was very drowsy and his urinary output was only 5 oz. in the first 24 hours after admission. It was acid, solid with albumin, and contained many casts and a little blood. The plasma bicarbonate was 0.0163 molar. After he had had grs. 210 of alkali, he passed 8 oz. of urine and after grs. 210 he passed 18½ oz. and the bicarbonate rose to 0.021 molar. After grs. 1380 he passed 26 oz. of urine, with a hydrogen-ion concentration of 8.3.

CASE 6. Chronic pyelonephritis.—The patient, a woman, aged 32, was admitted with headache, vomiting, purpura, uræmic twitchings, and almost complete suppression of urine. The blood-urea was 620 mg. per cent. She was given grs. 720 of alkali and passed 12 oz. of urine, which was neutral to litmus. The dose was maintained at grs. 720 for another 24 hours, and 32 oz. of urine were passed. The hydrogen-ion concentration was 7.2 and the urine contained 1 part per 1000 of albumin. The plasma bicarbonate was 0.033 molar and the blood-urea 550 mg. per cent. It was decided to continue the dosage at grs. 480 per diem, and later she passed 40 oz. of urine in the 24 hours.

CASE 7. Acute nephritis 15 days after tonsillitis.—The patient was a boy aged 8. The average output of urine was 2 oz. a day for four days. The blood-urea was 320 mg. per 100 c.cm. He was given grs. 180 of alkali a day by mouth. After three days he passed 10 oz. of urine. The following day diuresis set in and he passed 30 oz. The plasma bicarbonate was 0.0319 molar. On the next day he passed 12 oz. of urine.

In addition to the seven cases described 17 others have been treated similarly, and in a total of 24 cases the method only once failed to establish diuresis.

In this case, a man of 58, there had been complete anuria for four days after injections of salvarsan for tabes dorsalis. Alkalies in drachm doses were given by mouth two-hourly. After a total of grs. 1200 had been given, 7 oz. of neutral urine, containing albumin and a few casts, was passed. Twelve hours later he died suddenly. Post mortem there was marked neuritis and slight degeneration of the renal tubules. Even in this case the urinary secretion was presumably commencing.

In at least 12 of these cases it is a fair assumption that the production of diuresis was very largely the means of saving life.

Table showing the Duration of Suppression and the Plasma Bicarbonate.

Case.	Age in years.	Diagnosis.	Duration of suppression.	Plasma NaHCO ₃ molar concent.
A	20	Chronic parench. nephritis.	24 hours	0.0235
B	42	Acute nephritis and pregnancy.	3 days	0.0185
C	17½	Salvarsan poisoning.	3	0.022
D	4	Acute on chronic parench. nephritis.	3-4 "	0.0163
E	28	Heart failure.	24 "	0.0258
F	36	Cellulitis of arm. Old nephritis.	24 hours	0.0267
G	38	Salvarsan poisoning.	4 days	0.0265
H	26	Pre-eclampsia.	3 "	0.0246
I	16	Chronic pyelonephritis.	3 "	0.026

Significance of Plasma Bicarbonate.

The plasma bicarbonate was definitely below normal in every case where it was estimated. As it increased to a normal level more and more urine was passed. A low plasma bicarbonate does not of itself cause oliguria or anuria, as it is quite common in cases of heart failure, cirrhosis of the liver, Addison's anaemia, and many other diseases with a normal output of urine. There is evidence that an abnormally high plasma bicarbonate leads to renal damage, oliguria, and anuria. Brown and his co-workers have reported evidence of toxic nephritis associated with the alkalis of duodenal obstruction. Fischer and Selye (unpublished) have produced nephritis in dogs by the intravenous injection of alkaline salts, and the writer has described two cases of parenchymatous nephritis treated with alkalies which further illustrate this point.

It would seem, therefore, that anuria may be associated with either an abnormally high or an abnormally low plasma bicarbonate. Indeed, it seems doubtful whether anuria can develop or persist when the bicarbonate is normal. In order to prevent anuria, therefore, it is necessary to ensure that the plasma bicarbonate remains normal. Anuria associated with alkalosis is unlikely to be met with except in cases of high intestinal obstruction, as such cases the appropriate treatment with alkalies, per-chloride by mouth or by rectum in doses sufficient to reduce the plasma bicarbonate to a normal level. Experience has shown that it is unsafe to do this without facilities for the necessary estimations, as over-dosage may lead to a secondary and more persistent anuria. Acute nephritis constitutes an important exception, for in this disorder all the functions of the kidney are for a time in abeyance. Even if the blood bicarbonate is below normal large doses of alkalies may only accumulate in the blood and cause alkalosis. In these cases alkalies should only be given after other measures have proved ineffective, and only with caution, and, if possible, with blood controls. In none of our cases was blood present in the urine in more than microscopic amounts.

Prevention of Suppression and Anuria.

A decrease of the plasma bicarbonate has been found by the writer, by Cullen, Austin, Kornblum, and Robinson, and by others after prolonged exercise in normal persons, after comparatively mild exercise in nephritis, and after general anaesthesia by chloroform, ether, and nitrous oxide. Gamble, Ross, and Tisdall describe a lowered plasma bicarbonate in starvation. Anuria is especially liable to occur in persons in whom the kidneys are already damaged. It is in such cases that the superposition of any of the above conditions is therefore likely to result in suppression of urine and that alkalies can be used effectively to prevent this complication. The subjects of chronic nephritis of all types, however mild, and persons with damaged kidneys from any cause are bad operative risks from the point of view both of the anaesthetic and of post-operative shock (also associated with an acidosis). The danger consists very largely in post-operative depression of kidney function resulting in an acidosis of urine, which may or may not terminate fatally. Any remedy, therefore, which will tide them over the emergency will be of considerable value. It is almost impossible to obtain figures which show definitely that the prophylactic use of alkalies effectively prevents suppression, because it is never certain that in a given case such a complication must inevitably ensue. Nevertheless, experience has shown that in a large number of patients with renal damage, mostly chronic nephritis, in whom the plasma bicarbonate was maintained at a normal level by adequate doses of alkalies, the development of infections and inflammatory lesions and the use of general anaesthetics was not attended by any exacerbation of the kidney lesion which could be detected, or by oliguria or anuria, any of which might reasonably have been anticipated.

Experimental evidence is more easily obtained and points to the same conclusion. Kingo Goto showed that uranium nephritis in dogs was much less severe if sodium bicarbonate had previously been given by mouth. MacNider found that dogs with a naturally acquired chronic nephritis developed anuria after being anaesthetised with Grehan's anaesthetic, the principal ingredient of which is chloroform. These dogs did not have an initial acidosis (low bicarbonate), but developed this during the anaesthesia. The anuria was shown to be constantly associated with swelling, vacuolation, and necrosis of the convoluted tubular epithelium, and with the accumulation of fatty deposition showing a quantitative relationship to the degree of acid intoxication. In a further paper he showed that the prophylactic administration of alkalies

protected the kidneys of these naturally nephropathic dogs against the anæsthetic, so that anuria did not occur. Furthermore, when alkalies were not given and anuria followed the anæsthesia the intravenous administration of caffein citrate, theobromine sodium salicylate, pituitrin, urea, and glucose, failed to induce diuresis. When alkalies had been given before the anæsthetic, although anuria occurred, these same substances produced an increased flow of urine. These experiments suggest that diuretics are not effective unless the plasma bicarbonate is first at a normal level. This would explain their comparative failure in the treatment of chronic nephritis with œdema, a condition in which the plasma bicarbonate is often below normal and in which alkalies are of considerable value.¹ MacNider also showed that a 0.9 per cent. solution of sodium chloride is not equally effective in preventing anuria in dogs in similar experiments. Andrews¹⁰ found that the amount of water that it was possible for a dog to excrete after the intravenous injection of glucose was directly proportional to the alkalinity of the blood (plasma bicarbonate). If the carbon dioxide combining power of the blood was below a "critical point" of 45 vols. per cent. diuresis did not occur, as all the water in the body was "fixed" or held relatively firmly by the colloids. Above this level water is more loosely held by the colloids and diuresis occurs. He noted also that above the "critical point"—that is, at the alkaline end of the scale—less water was excreted. These results agree remarkably with those obtained by the writer,⁹ who showed that, in some cases of chronic parenchymatous nephritis, diuresis and subsidence of œdema occurred under treatment with large doses of alkalies when the plasma bicarbonate reaches a "critical level." The diminished output of urine when the plasma bicarbonate rises above the normal has also been found by the writer in cases of chronic nephritis and is discussed elsewhere.¹ Liotta¹¹ found that prolonged administration of sodium salicylate in rabbits caused marked changes in the kidneys, but that when sodium bicarbonate was added to the sodium salicylate these changes were not found. Finally, Weiss¹² showed that the administration of alkalies is by far the most successful method of combating mercuric chloride poisoning in man. The toxic action on the kidneys is largely prevented, so that acute nephritis and suppression of urine are less likely to develop or to prove fatal. There would therefore seem to be abundant evidence, both clinical and experimental, that kidney damage and anuria can be prevented by the prophylactic use of alkalies under a variety of conditions.

Dosage.

In the prevention of anuria by the administration of alkalies a preliminary estimation of the plasma bicarbonate should always be made. In this way only can effective protection be secured. No doubt the routine use of alkalies in these circumstances in amounts sufficient to render the urine alkaline to litmus will prove sufficient in a number of cases, and, given in this way with care, probably little harm would result. Failures, however, are certain with such a haphazard and inadequate procedure. Apart from drawing attention to the possible dangers of empirical dosage, no definite rules can be given, as the amount of alkali needed must be assessed from time to time by the blood findings.

NOTE ON THE ACTION OF OESTRIN ON THE ISOLATED UTERUS

SENSITISED WITH PITUITARY EXTRACT.

By ELEANOR M. SCARBOROUGH, M.B.,
M.Sc. Lond.,

READER IN PHARMACOLOGY IN THE UNIVERSITY OF LONDON.

(From the Pharmacological Laboratory, London (R.F.H.) School of Medicine for Women.)

In a recent paper in *THE LANCET* Bourne and Burn¹ have described the synergistic action of œstrin and pituitary extract upon the isolated uterus. This synergism is demonstrated by the markedly augmented contraction which pituitary extract evokes when used in the presence of a small dose of water-soluble œstrin.

A series of experiments, somewhat similar but with the sequence of application of drugs reversed, has been in progress here during the last few months. Doses of water-soluble œstrin, large enough to produce a definite uterine contraction have been used, and the contraction evoked by a constant dose of œstrin recorded before and after sensitisation of the uterus with pituitary extract. The results of this series of experiments confirm the findings of Bourne and Burn.

The water-soluble œstrin used throughout has been prepared by the method of Laqueur, Hart, and de Jongh.² The preparations produced characteristic vaginal smear reactions in the ovariectomised rat, as described by Coward and Burn,³ but no standardisation of the preparations has been attempted. The solutions grew mould on keeping and gradually lost their activity. The dose used throughout was that which was found by trial to be the smallest dose producing a definite uterine contraction.

Method.—The uterine horn of the virgin guinea-pig (10 to 12 weeks old) was suspended in 100 c.cm. of Magnus's solution, through which a constant stream of oxygen was passed. The temperature was maintained evenly at 38° C. Drugs under consideration were added to the saline, which was changed after each drug action without altering the other conditions of the experiment. Spontaneous uterine contractions, when present, were almost or completely eliminated by adjusting the weight of the writing lever.

Results.—Control experiments showed (a) that the sensitiveness of the uterus to pituitary extract is increased after it has been suspended for half an hour in 100 c.cm. saline containing 0.01 unit of pituitary extract (Fig. 1); (b) that the contraction produced by a second dose of œstrin is either similar to, or somewhat smaller than, the contraction caused by the first dose, when the uterus is suspended in saline during an interval of half an hour between the two doses (Fig. 2).

In 30 experiments a contraction was recorded in response to a dose of œstrin. The œstrin was then removed and the uterus sensitised with pituitary extract, as in the control experiments. After washing out the pituitary extract the contraction produced by

FIG. 1.

Showing increased sensitiveness of the uterus to pituitary extract. At P1 and P2 0.02 units were introduced, at S the drum was stopped and the uterus remained suspended for half an hour in saline + 0.01 units.

a second equal dose of œstrin was recorded and compared with the first. Sixteen of these experiments showed an increase in the œstrin contraction after sensitisation (Fig. 3). Eight experiments gave a negative result, the second contraction being smaller than the first. The remaining six experiments gave no characteristic result as large spontaneous uterine contractions were exhibited and the contractions evoked by drugs were all of equal and presumably

FIG. 2.

Showing the effect, at O1 and O2, of equal doses of œstrin. At the drum was stopped and the uterus remained suspended for half an hour in saline between the two doses.

conditions, rendered more sensitive to the action of œstrin also. Discrepancies due to the varying original sensitiveness of uterine muscle may explain the high proportion of negative results. The phase of the oestral cycle of the animals from which uteri was obtained has not, as yet, been taken into account in these experiments.

The increase in sensitiveness of the uterus to œstrin after pituitary extract is comparable with the synergistic action of the two drugs when used together. Bourne and Burn suggest that the synergistic action of œstrin is an important factor in determining the onset of parturition by enhancing the sensitiveness of the uterus to pituitary extract. These workers regard their hypothesis as an alternative to that of Dixon and Marshall,² who describe an increased output of secretion from the posterior lobe of the pituitary gland, occurring in response to an interstitial ovarian

maximal size; it was thus impossible to demonstrate an increase of sensitiveness with pituitary extract. In these cases it is probable that the uterus was removed from the animal during œstrus, when, according to Burn and Dale,⁴ the muscle is excitable and prone to acquire a large automatic rhythm.

Discussion.

These results indicate that the isolated uterus, sensitised with pituitary extract, is, under certain

FIG. 3.

Showing the effect, at O1 and O2, of equal doses of œstrin. Between ↑ ↓ the uterus remained suspended for half an hour in saline and of units of pituitary extract.

hormone, and rendering the uterus supersensitive and highly responsive to other forms of stimulation at the close of pregnancy. These two conditions may, however, be considered as co-existent rather than alternative, and the production of a maximal uterine sensitiveness at the onset of parturition may be regarded as the combined rôle of the two ovarian hormones, the development of an augmented response to pituitary secretion producing, concurrently, an augmented response to the presence of œstrin.

Clinical and Laboratory Notes.

A NOTE ON THE

TREATMENT OF RICKETS WITH IRRADIATED ERGOSTEROL AND ULTRA-VIOLET LIGHT.

BY ELLA FERRIER PRINGLE, M.D., M.R.C.P. EDIN.,
D.P.H. GLASG.,

LATE ASSISTANT MEDICAL OFFICER (MATERNITY AND INFANT WELFARE), BURGH OF PAISLEY.

IN view of the fact that, in Paisley, we experienced considerable difficulty in inducing mothers to bring their rachitic children regularly three days a week for ultra-violet light treatment, we decided to try a certain number of these children with radiostol (irradiated ergosterol). Accordingly, we selected 42 cases of early, medium, and late rickets, and each child was given one tablet of radiostol daily. The results of treatment were, in most instances, very good indeed. We found that the early and medium cases showed the greatest improvement in the shortest time. Children from 1 year to 14 months old who had not erupted any teeth, and who were neither attempting to walk nor stand, after four weeks' treatment walked unaided, and dentition was well established. Each succeeding month of treatment showed steady improvement, particularly in these two directions. In some instances the general condition of the children improved to some extent but not nearly so markedly as the local condition. The effects of ultra-violet light were in noticeable contrast to the changes seen with radiostol, for after a course of light the most striking improvement was that seen in the patients' general condition. After a short course of treatment the children lost their restlessness, slept well, became happy and contented, and did not cry when handled. Advanced cases of rickets with genu valgum or varum improved slowly under treatment with ultra-violet light.

The conclusions one may draw from the above are as follows: 1. Radiostol is a valuable agent in the treatment of rickets in young children. Though it cannot take the place of ultra-violet light therapy, it is undoubtedly of great service for children who are unable to attend the sunlight clinic regularly. The general condition of such children does not show the same rate of improvement as does the local condition. 2. Rachitic children respond rapidly to treatment by ultra-violet light rays, as is evidenced by the improvement which takes place in their general condition, even after a short course. Rachitic deformities definitely improve under such treatment, though a prolonged course may be necessary to effect a cure.

Edinburgh.

A CASE OF

INFECTION OF THE MENINGES BY *BACILLUS LACTIS AEROGENES*.

BY A. DEANE, M.D. ABERD.

SENIOR PHYSICIAN TO THE PRINCESS ALICE MEMORIAL HOSPITAL, EAST DUNDEE.

AND

GEOFFREY SHERA, M.D. CAMB.

CLINICAL PATHOLOGIST TO THE HOSPITAL.

It has been stated by Dr. Russell Brain and Dr. F. C. O. Valentine¹ that "general infections, with meningeal involvement, by bacilli of the Friedländer type are occasionally met with, but a mucoid bacillus of these cultural characters (referring to a type of *B. mucosus capsulatus* which formed only acid and no gas in certain sugar media) has not previously been isolated in these laboratories (London Hospital), either from the blood or the spinal fluid." We have therefore thought it worth while to report a case of

¹ *The Lancet*, 1928, I, 555.

infection of the meninges by an allied capsulated mucoid bacillus—namely, *Bacillus lactis aerogenes*—in this instance secondary to suppurative cholecystitis.

The patient, Mrs. A., aged 71, was admitted to hospital on May 11th on account of persistent vomiting and pyrexia. A week previously she had had a rigor, with a temperature of 102° F. Since then she had been vomiting frequently and was very constipated.

On admission her temperature was 101°, pulse-rate 132, and respiration-rate 40. She seemed lethargic and very tired, and complained of persistent vomiting and feeling very weak. She was very fat; there was no abdominal pain, tenderness, or rigidity, nor any palpable tumour. There were moist râles at both bases. The next day she was in a state of low delirium, and the following day at noon she had a rigor (temperature 101°) and became deeply comatose and lay curled up on her side in bed with her head forward. Her respirations remained rapid and the pulse-rate 100 to 120; moist râles were more numerous over the chest. Blood-stained pus began to flow from the nose and she died in the afternoon.

Post-mortem examination (G. S.) showed obvious meningitis with green pus over the vertex beneath the pia-arachnoid, which was raised up in blebs by bacterial gas formation. The base of the brain and fourth ventricle were also purulent. The middle ear and ethmoidal cells were clear. The nose showed some localised purulent discharge of a chocolate colour. The skull was of abnormal thickness and density. The muscular tissue of the heart was very pale and flabby. There was thickening and incompetence of the mitral valve, and the aorta showed a moderate degree of atheroma. The lungs were congested at the bases. The liver was large, soft, and fatty in texture. The gall-bladder showed one small faceted stone lying in a bag of creamy pus. The spleen was enlarged, diffuent, and septic in type. The kidneys were small and pale; some chronic interstitial changes were evident. The capsule, however, peeled easily.

The cause of death was held to be septic meningitis due (as subsequently ascertained) to infection via the blood stream by *Bacillus lactis aerogenes* and secondary to suppurative cholecystitis. Films from meningeal pus and gall-bladder pus showed many large Gram-negative capsulated bacilli. Some of the forms were very long. The cultural reactions are contrasted in the following table with those of two other bacilli—namely, Brain and Valentine's strain of *B. mucosus capsulatus* and Stitt's description² of *B. mucosus capsulatus*.

	<i>B. lactis aerogenes</i> .	Brain and Valentine's organisms.	Stitt's organism.
Type of growth on McConkey's medium	Pink, profuse, and mucoid.		Colourless, profuse, and mucoid.
Gram-staining	Negative.		
Filaments	Present in films.	?	Present in films.
Motility	Non-motile.		
Gelatin	Not liquefied.	?	Not liquefied.
Serum	Negative.	?	Optional (±).
Indol formation	Positive.	?	" "
Voges-Proskauer test	Positive.	?	" "
Animal pathogenicity.			
Milk	Acid and clot. in 24 hours.	Acid only.	Acid and clot.
Dextrose	Acid and gas.	" "	Acid and gas.
Lactose	" "	" "	No change.
Mannite	" "	" "	Acid and gas.
Salicin	" "	?	" "
Saccharose	" "	?	Acid and gas.
Maltose	" "	?	" "
Dulcitol	No change.	" "	" "
Inulin	?	No change.	?

? = not mentioned.

It will thus be seen that these three strains of bacilli differ in certain interesting particulars. Whereas our strain of *B. lactis aerogenes* agrees absolutely with Stitt's, and also Castellani's³ description of that germ, Brain and Valentine's strain differs from Stitt's description of *B. mucosus capsulatus* in several striking points. First, it does not ferment lactose, and secondly, no gas is formed, nor is milk clotted. These

differences are certainly more academic than clinical inasmuch as the bacilli can cause septicæmia and meningitis and are obviously closely allied bacteriologically. The clinical obscurity and insidiousness of the meningeal invasion were a feature of our case.

Unlike bacilli of the Friedländer type, *B. lactis aerogenes* produces gas in lactose, but here again we have a closely allied organism. The justification for publishing this case was the rarity of meningeal infection by *B. lactis aerogenes* group organisms as pointed out by Brain and Valentine in their recent paper, as opposed to the not uncommon type of meningitis associated with Friedländer's bacillus.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS.

At a meeting of this Section on Dec. 7th, Dr. ASHLEY DALY, the President, in the chair, a paper on

PRELIMINARY MEDICATION IN ANÆSTHESIA

was read by Dr. STANLEY ROWBOTHAM.

For the nervous patient, he said, the preliminaries to the actual operation—the journey to the theatre and the taking of the anæsthetic—were fraught with fear and aversion, and he considered that everything possible should be done, within the limits of safety, to blunt sensibility so that the unsettling nervousness would be much less real. The customary gr. $\frac{1}{4}$ of morphine was not enough. The wind could be a good deal tempered to the shorn lamb by the use of ether per rectum, but the addition of hyoscine he had found to be a distinct advantage. Dr. Rowbotham had been trying to find a way of protecting the nervous system and causing in the patient such a profound sleep before the actual anæsthetisation and while he was still in bed that it would be impossible to arouse him out of it, so that not only would apprehension be abolished but true shock would be diminished. This it was nearly always possible to accomplish with paraldehyde alone, or with hypodermic injections of morphine, heroin, or hyoscine. During the investigation it became clearly evident that combinations of drugs acted more powerfully and for longer periods than did any separate drug of such combination used alone. It was believed by some that this was because the drugs acted on different cells. Chloroform was so greatly reinforced in its action when used in combination with other drugs that the speaker did not think it was safe to employ it following a complete preliminary paraldehyde and morphine narcosis.

For determining dosage Dr. Rowbotham gave four groups of cases:—

1. Children under 7 years of age; under-sized older children; very feeble young subjects; those with low blood pressure; those who had had a heavy blood loss, and who had had a rise of temperature for some days.
2. Normal adults, and children over 7.
3. Very nervous patients; alcoholics; athletes over 25 years of age.
4. Cases of Graves's disease.

He propounded an elaborate table of dosages for each class. In Graves's disease, he said, it was very difficult to narcotise the patients. As operations upon them were nearly always done under local anæsthesia, it was very important to have them absolutely quiet and asleep. For them he used progressive doses, stopping short when the result had been attained. For some days before operation he tested the reaction of the patient to the drugs to be employed. The action of these drugs was more profound in patients with a low blood pressure, those who had had severe hæmorrhage, who had suffered shock, or long-standing sepsis, hence the quantity used must be less.

After giving a detailed account of the actual technique used, Dr. Rowbotham said he did not think paraldehyde alone was contra-indicated for abdominal

operations. The most important contra-indication to this preliminary medication was the necessity of using chloroform as the general anæsthetic. The method he was now advocating had achieved its object very successfully: indeed, in some cases, patients on awaking to full consciousness long after the operation, asked quite innocently when it was likely to take place.

Discussion.

Dr. JOSEPH BLOMFIELD agreed that it was very important that the anæsthetist should make the patient as comfortable and as free from after-effects as Dr. Rowbotham seemed to do with paraldehyde. Not much detail had been given, however, concerning the nature of the cases in which he brought it about. The chief point was the long sleep which ensued after the operation. From the patient's point of view this was doubtless desirable, but there were objections to it. It meant, for instance, that for hours the patient was breathing so feebly that the lungs were inefficiently distended. From this pulmonary congestion serious trouble might arise. And in operations involving the air passages there was the question of blood trickling into places where it was not desired in an insensitive patient. If Dr. Rowbotham would show that he obviated these dangers the method had much to commend it. Avertin seemed to be, in many respects, at least equal to paraldehyde, in some ways even superior. With avertin, however, some anæsthetic had to be used in order to be safe.

Dr. J. W. MACILL said he had had some marvellously good results with paraldehyde in his private practice. He did not use the method in every case, but found it particularly valuable for nervous children. Much, he thought, depended on the type of nurse on whom one relied to give the rectal injection. It should be warned before being given; and if olive oil was used it was unnecessary to employ chloretone. Dr. Rowbotham's procedure had the disadvantage that it required a visit to the patient on the previous evening. The method was contra-indicated in cases associated with much sputum, such as bronchiectasis, for such a patient should be active immediately after the operation so as to be able to empty his cavities.

Mr. F. T. EVANS asked whether Dr. Rowbotham got cases of extreme restlessness after using paraldehyde. He had heard of one patient being practically maniacal for some time after the operation, even gr. $\frac{1}{2}$ morphine failing to quieten him.

Dr. Z. MENNELL expressed a preference for giving an anæsthetic by the upper air passages rather than by rectal injection. He did not think the contention that paraldehyde was quite safe could be maintained. Before the war it had been given intravenously, but two deaths in quick succession had checked that method. Some people had an idiosyncrasy towards the drug, and when once a dose had been given per rectum it was practically irrecoverable. It could not be good for chest operations or for cases in which there was a hidden hæmorrhage; nor yet for tonsil and adenoid cases, for the children were apt to be asleep while blood was continually trickling into the stomach. A further class of cases in which the method should not be used were those having a high intracranial pressure. The quiet and comparative absence of anxiety on the part of the patient could easily be equally ensured by means of twilight sleep, whose intensity could be modified at will. Some patients were sure to suffer from proctitis after the use of paraldehyde.

Dr. C. H. HUNT said he had not had experience of Dr. Rowbotham's method, but at present there was a tendency to dispense with morphine, as many surgeons considered that patients were not so well after it. He agreed with Dr. Menzell about the danger of a patient having an idiosyncrasy concerning paraldehyde. Dr. HUNT pointed out that Dr. Rowbotham's method was most valuable for children, and that he had found it very useful during a three years' trial. Perhaps it added to the staff, as it must be given

slowly, otherwise the child might reject it. Paraldehyde, however, should admittedly only be used in selected cases.

Dr. H. A. RICHARDS thought the question at issue was: Should the feelings of the patient be considered or his safety? He had had very little experience of the method, but for nose and throat operations it seemed almost reprehensible to use it. If there were a throat case without bleeding it might be allowable to give paraldehyde, but not when bleeding occurred. He did not feel favourably disposed towards the method.

The PRESIDENT said he did not employ even morphine before the operation, as he had found that some patients had been given it only a short time before the induction of the general anæsthesia was due. The method described should not be used in any case in which bleeding into the larynx was probable. After paraldehyde the condition of patients as they reached the operating theatre was ideal; if only they could be reawakened shortly after the operation matters would be all right. The sooner after operation the patient became conscious and active the better. Sleep could later be induced by a drug if necessary.

Dr. ROWBOTHAM, in reply, agreed it was not possible to use the paraldehyde in hospital as a routine. The timing meant more work for the nursing staff. He had not tried avertin, but he hoped to be able to do so. Most patients under the influence of paraldehyde and morphine got a lower blood pressure. The one or two cases of restlessness which had come into his experience he had attributed to his use of hyoscine. People who paraldehyde had been given to a patient and it was found that he was intolerant of it, washing out the rectum would, he thought, recover some of it. It was discovery of some persons with an idiosyncrasy towards paraldehyde should not be regarded as a serious argument against its use.

SECTION OF THERAPEUTICS.

At a meeting of this Section on Dec. 11th the chair was taken by Prof. J. A. GUNN, the President, and a discussion on

PURINES AS DIURETICS

was opened by Prof. E. B. VERNEY. He began by reviewing the work of Bowman and said that the theory which he would adopt was practically that proposed by Bowman in 1812, except that the implicit belief of that authority in the expression of a watery fluid through the glomerular capillaries would be extended to include the explicit belief of Ludwig in the mechanical nature of this transference. It was now almost universally admitted that the function of the glomerulus was to allow the passage of a protein-free fluid having the same composition as an ultra-filtrate of the blood plasma, and that all the water of the urine is primarily eliminated at the glomerulus. To Bowman's belief, that the specific urinary constituents were actively secreted into the watery fluid flushing the lumen of the tubule, would be added Ludwig's conception that the tubule cells concentrated the glomerular filtrate by absorbing certain useful substances were reabsorbed and others were actively secreted by the tubular cells into the filtrate. It was not known where these processes were carried out, but there was a little evidence that water was reabsorbed lower in the tubule than urea was excreted. The kidney could be regarded as made up of a large number of renal units, each consisting of a capsule, a glomerular capillary bed, Bowman's vas afferens, a collecting duct, the lumen of the tubule, and a collecting duct. The human kidney was composed of about 5000 of these units. The output of water from any renal unit could theoretically be increased (a) by increased elimination at the glomerulus, and (b) by decreased absorption from the tubule. The total elimination could also be increased by calling into use units which were not previously functioning. A. N. Richards had shown that the

glomeruli of the frog's kidney alternated in function, some opening up while others closed down. The injection of such substances as urea and caffeine into the blood stream increased the number of active units. This large reserve of the kidney explained its diuretic response to caffeine and urea and the absence of a response when the reserve had been reduced by disease.

Glomerular Diuretics.

The amount of filtrate produced by a single glomerulus could be increased by increasing the filtrate pressure and by increasing the surface or permeability or both. The effective filtrate pressure was the difference between the lateral pressure in the glomerular capillaries and the osmotic pressure of the plasma proteins, and either of these could be varied. Richards had also shown that the capillary loops in any one glomerulus of the frog's kidney were subject to changes in patency, so that the filtration surface might vary extensively. The presence in the blood of urea or glucose, therefore, increased not only the number of active glomeruli, but also the number of active capillary loops in each glomerulus. It was impossible at present to determine the rôles played respectively by the various factors.

W. von Schroeder in 1886, and Phillips and Rose Bradford in 1887, had studied the xanthin bodies, and the former had shown that caffeine usually had no diuretic effect in rabbits under the influence of morphia, but that it acted strongly when chloral was used. He had attributed this result to a stimulation of the vaso-constrictor centre by morphia. If one kidney was denervated under morphia caffeine caused a marked diuresis on that side only. v. Schroeder had therefore concluded that caffeine had a double action on the kidney, an indirect central vaso-constrictor action, and a direct effect on the secreting epithelium. The latter, he had held, was only effective when the former was inhibited, as, for instance, by section of the renal nerves or injection into the blood of some substance like chloral, which protected the vaso-motor centre. The increased output of water was accompanied by an increased output of total salts. Caffeine increased the output of urine in the normal dog very slightly, if at all. v. Schroeder had rejected the glomerular filtrate hypothesis because caffeine produced diuresis when the blood pressure was considerably lowered by chloral, but this conclusion was not justified, as he had not estimated the blood flow. Phillips and Bradford had measured the change in volume of the kidney and the blood pressure in caffeine diuresis and had found that the diuretic effect was not dependent upon the vaso-dilatation or upon the blood pressure. Usually there was considerable expansion at the time of diuresis, but occasionally the diuresis was obtained without this. Changes in the kidney volume did not, however, indicate similar changes in the blood flow, but these results suggested that the rate of urine flow depended on the rate of blood flow. In 1901 Gottlieb and Magnus had obtained similar results, but had accepted v. Schroeder's hypothesis on account of the occasional occurrence of diuresis with increased kidney volume. In 1905 Loewi had concluded that the increased blood flow was the cause of the diuresis. There had been, therefore, no agreement as to whether caffeine could or could not increase the urine without a concomitant increase in blood flow. Richards and Plant in 1915 had shown definitely that caffeine produced increased elimination despite a constant blood flow, and recently Cushny and Lambie had found that caffeine diuresis began before and lasted long after the acceleration of blood flow. They thought that it caused diuresis by reducing the resistance of the glomerular capsule to filtration. It would be premature to deny that the diuretic effect was largely due to an increase in the rate of glomerular filtration arising either from an increase in the capillary pressure, or from an increase in the surface area, or from both. These factors might change without any alteration in the blood flow. The changes in composition of the urine during caffeine

diuresis pointed to a glomerular rather than to a tubular mode of action; there was an increased nitrogen and chloride output at the height of the diuresis, varying with the percentage amount present in the urine before the administration of the drug. There was some evidence that caffeine was ineffective in the presence of a glomerular lesion, but effective when the tubular cells were disordered. The dimethyl-xanthins, theobromine, and theophyllin probably acted in the same way as caffeine. Theophyllin was the most potent of that group.

Such substances as urea and sulphates would presumably act by increasing the molecular concentration of the fluid in the tubules, but it was probable that their effect was partly glomerular in origin.

Discussion.

Dr. E. P. POULTON said he had been disappointed with the clinical action of the caffeine group. He described a case in which the glomeruli had been completely obliterated and the tubules normal, and the patient had had a blood-urea value of 500 mg. per cent., yet she had appeared well until within a few hours of her death. In another case the tubules had been degenerated and the blood-urea normal. He could not reconcile these cases with the statement that urea was excreted by the tubules.

Dr. GEORGE GRAHAM wondered whether the doses in common use were the right ones.

Dr. R. D. LAWRENCE asked whether diuresis had any effect on the renal threshold.

Dr. F. PARKES WEBER mentioned cases of pure parenchymatous nephritis, now called pure nephrosis, in which the output was greatly diminished without a rise in the blood-urea. Diuretics failed completely, and he believed that there was a mechanical blockage, the tubules being so swollen that water could not pass through.

Dr. KINGSTON BARTON recalled a case of auricular fibrillation, resulting from renal disease, in which digitalin had failed to produce diuresis and diuretin had been pressed as well. He remarked on the significance of the degree of alkalinity of the blood for diuretic action.—Dr. A. A. OSMAN said that there was good evidence, both experimental and clinical, that if the blood was either too alkaline or too acid no diuretic would produce diuresis. He suggested that morphine inhibited diuresis by virtue of its depressing effect on the respiratory centre.

The PRESIDENT pointed out that the action of drugs could only be discussed in relation to dosage, and commented on the difficulty of correlating experimental and clinical work, since the administration in the former was usually intravenous and in the latter oral. He asked whether the increased excretion of water would not lead reflexly to local vaso-dilatation. Chloral was a powerful dilator of the peripheral vessels, while morphine slightly contracted them in the rabbit.

Dr. POULTON recalled Brodie's theory that the glomerulus had merely a mechanical pumping action.

Dr. OSMAN pointed out that the diuretics would increase the flow of urine up to a certain degree of acidity or alkalinity of the blood, but that beyond that point oliguria supervened.

Dr. WEBER described pure nephrosis as a functional imitation of what happened in mercuric chloride poisoning.

The PRESIDENT pointed out that the mucous membrane of the large intestine performed an absorbing and an excretory function simultaneously; it was therefore reasonable to postulate a dual function for the kidney tubule.

Dr. BARTON said that cases of slow cirrhosis of the kidney without tubular nephritis might throw some light on urea excretion. The patients had high blood pressure and passed three or four pints daily but were able to live to old age without complaint.

Prof. VERNEY, in reply, agreed that it was impossible to correlate physiological and pathological findings, and thought that the physiologists might have to modify their outlook. Evidence against Brodie's

theory had been provided by Richards's experiment in which he had removed fluid direct from the glomerular capsule and found that it contained no protein, but chloride and glucose in approximately the same proportions as the blood plasma. He had calculated that the volume there was enough to account for the whole quantity secreted. If the rate of urine flow were increased experimentally glycosuria might be produced, presumably because the tubule cells had no time to reabsorb the sugar.

MEDICAL SOCIETY OF LONDON.

At a meeting of this Society on Dec. 10th the President, Dr. J. WALTER CARR, in the chair, a discussion on

SACRO-ILIAC PAIN

was opened by Dr. WILFRED HARRIS, whose address will be found on p. 1230.

Mr. P. J. VERRALL dealt with the subject from the surgical aspect. In doubtful cases, he said, antero-posterior skiagrams would clinch the diagnosis. Until recently X rays were of little value as a means of diagnosis, as the joint was tortuous; even stereoscopic views often failed to clear up a doubt. He agreed with those who said that if arthritis showed in a joint skiagram it must be of advanced degree. The fact was that one had to rely almost entirely on clinical evidence to arrive at the diagnosis, the radiologist not being able to give much help. Mr. Verrall differed from those who said that all affections of this joint were very rare, though he could not go so far as one speaker in a recent discussion, who declared he had treated 1500 cases of subluxation. Conceptions in regard to sacro-iliac conditions were now on surer ground. Apart from tubercle and strains and subluxation, he agreed with Dr. W. Yeoman¹ that arthritis of the joint was not uncommon. It was supplied by all the nerves near it, and any pain in their distribution could easily be understood by thinking of it as referred. The most severe arthritis in that region was that due to gonococcal disease, which was more common than many supposed; indeed, the sacro-iliac stood high in the list of joints affected by that disease. A strain might be a starting-point of tubercle. There was considerable variation, in different persons, in the long axis of this joint and in the degree of laxity of its ligaments. The joint often became ankylosed in males, seldom in females. The ligaments of the joint took a large part of the superincumbent body-weight, and it had been found that too early weight-bearing after labour was a fertile source of trouble in the joint; so that it was not surprising that a second and better managed puerperium sometimes, as in the case of subinvolution of the uterus from the same cause, cured the trouble. Sometimes the cause of subluxation was the fall of a heavy body on the back while the patient was stooping.

In discussing the diagnosis Mr. Verrall said the symptoms were pain in the back or so-called sciatica, either of which might be due to many causes. If pain was increased by a jar it was suggestive, but this was not a reliable sign. In severe cases the gait of the patient was pathognomonic, especially when he tried to go upstairs. In ordinary arthritis of the hip the joint was stiff and painful in all positions, but the patient with sacro-iliac disability could be observed to seek a comfortable position. The tenderness which accompanied a severe case led to an exaggeration of the symptoms. In mild cases there was a tendency to deviate the body to the affected side, whereas in bad cases the deviation was away from the affected side. Also the early case showed considerable lateral sway, but the advanced case had a flat, ataxic vertical line of stance and a normal, inspection without a swelling, abscess formation, and sinus, associated with wasting of the gluteal and other

muscles. And in sacro-iliac disease there might be tenderness of the sacro-sciatic notch. Superficial tenderness of the joint and just below it was common and must be carefully distinguished from deep tenderness. A displaced uterus in women or a chronically loaded rectum in either sex were among the causes. In association with Prof. Louise McIlroy he had investigated causes and found that uterine displacements were a less common cause and constipation a more common one than was thought 20 years ago. Compression of the ilia would press two cartilaginous surfaces together, while forcible separation of the anterior superior spines would cause pain if they were inflamed. A positive result of this test he regarded as conclusive.

With regard to treatment, if sacro-iliac subluxation was accepted as a clinical entity, reposition, followed by support, was indicated. If the upper ilium was rotated forward full flexion of legs and spine would reduce the lesion. In other cases in which judgment could be made from the extent of the lordosis—such as that following relaxation due to parturition, in which subluxation was in the reverse direction—reposition was best secured by placing the patient on his face and hyperextending the hip on the affected side, with counter-pressure exerted by the other hand on the opposite side. This reduction should be followed by the wearing of a support or broad band, stretching round the pelvis, with a pad over the affected joint, and the patient should rest in bed for a few days with a lumbar support. Most of the belts used for this condition did not reach low enough; the belt should just clear the seat of the chair when the patient was seated and should be below the great trochanter. In front the belt should encircle the pelvis and bind it firmly together, while it reached a point low enough to hold up the lower abdomen without cutting the thighs when the patient bent forward. Many cases of relaxation could be efficiently dealt with by the more or less permanent wearing of such a belt. In cases of arthritis in which no operation was called for, a belt would relieve the condition while search was made for the cause and treatment was instituted. In sacro-iliac trouble little or no benefit was obtained by local physiotherapeutic measures, such as diathermy and massage.

Operative measures would be directed towards obtaining internal fixation of the joint. Tuberculous sacro-iliac disease was so dangerous to life that severe treatment was often justified; but resection was a severe operation, and should never be undertaken for minor lesions. For the last few years he had been employing a method of grafting which he described in 1921—i.e., placing a graft from the tibia across and between the posterior superior spines, under the erector spinae muscles, following the principle of the tie-beam to support a house in danger of falling. It had the advantage of being a simple method, and it only required 15 minutes to carry out. And in infected cases (e.g., tuberculous) the operation did not interfere with the infected area unless there was a dorsal abscess or sinus. He had been well satisfied with the results from it when cases were severe enough to require it, which admittedly was fairly seldom.

Dr. JAMES BRAILSFORD (Birmingham) showed a series of skiagrams from 3000 in his collection, to illustrate various accidents, deformities, and diseases of sacro-iliac joint. He said that many of the deformities in this region were not recognised until later in life—i.e., when more strain was put on the region, especially the joint. In some cases there was a separate centre of ossification for the fifth lumbar transverse process.

Dr. C. B. HEALD, who spoke from personal knowledge of the symptoms of sacro-iliac disability, said that an important point was the cat-like cautious way in which the sufferer went about, deciding that he might get into one of the neatly painful postures, particularly in assuming the erect posture after bending. Immediately after the acute pain had gone the legs felt large and "wooden," and there was a tingling of the hands.

Dr. H. A. ELLIS said it was always important to examine the condition of the urine in these cases, especially as to its specific gravity. If the urine was of high concentration the pain would not be got rid of until the urine was put right. If the case was one of osteo-arthritis one could be sure of the diagnosis if the urine was of high specific gravity. In both types—high and low gravity urine—there might be an excess of uric acid.

Dr. WILFRED HARRIS, in reply, thanked Dr. Brailsford for his excellent series of skiagrams. He asked Mr. Verrall what were his views on the use of anaesthetics when doing manipulations. Some people preferred to do manipulations without giving a general anaesthetic.

Mr. VERRALL, in reply, said he thought it impossible to do manipulation of the sacro-iliac joint or spine without using a general anaesthetic. He gave a demonstration of his method of carrying it out.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this Society was held on Nov. 22nd, with Mr. A. L. CANDLER, the President, in the chair.

Dr. C. H. MILLER showed a man, aged 54, with splenomegaly, anaemia, and gout.

The patient gave a history of gout dating back several years, and he had lost weight recently. There was no vomiting and no loss of appetite. In September, 1928, he first noticed pain immediately after dinner, this lasted several days and then began to subside. The family history was good and the man could not remember any serious illness.

The chief points of interest in the case were (1) the general colour, (2) the tophi on the pinnae, (3) splenomegaly, and (4) enlarged glands in the groins and elsewhere. A blood count on Sept. 20th, 1928, showed haemoglobin, 22 per cent.; red cells, 1,910,000; and white cells, 10,400. Differential count: polymorphs, 60 per cent.; lymphocytes, 34 per cent.; large mononuclears, 5 per cent.; eosinophils, nil; and mast cells, 1 per cent.

There was slight variation, said Dr. Miller, in the size and shape of the red cells, but no nucleated cells were seen. The Wassermann reaction was negative. Four weeks after admission a further blood estimation showed a slight rise in haemoglobin and an increase in the number of red cells to 4,000,000. The leucocytes now totalled 8400, with a differential count within normal limits. Stimulated by the results obtained with liver in a case of pernicious anaemia in the neighbouring bed, he had given it a trial here also, but with no advantage. More good seemed to be referable to chlorophyll-carrying agents and atophan.—Dr. R. V. SOLLY had found it impossible to classify the affection from the point of view of the blood picture.—Dr. T. R. WHIPHAM remarked upon the persisting low figure of the haemoglobin in the second count and also upon the absence of any nucleated red cells as evidence of the blood regeneration which might be presumed to have taken place on comparing the two counts.

Mr. R. WAYLAND SMITH showed a woman, aged 29, suffering from superficial gangrene of the skin following a burn. Some 18 months ago she had burnt her thumb and this continued to suppurate, in spite of energetic treatment, and eventually reached a condition of dry gangrene necessitating amputation of the thumb in July of this year. Since then she had the developed patches of superficial gangrene on the wrist and hand of the same side. No sugar had been detected in the urine or other cause discovered for this obstinate condition. *Staphylococcus aureus* was alone isolated from the pus and vaccines so obtained were worked up to 700 millions. Locally Mr. Wayland Smith had tried dichloramine dressings and ultra-violet rays. He invited the opinion of the meeting as to diagnosis and treatment.—Mr. NORMAN LOCK suggested the possibility of scleroderma and, all other

means failing, the advisability of performing sympathectomy of the brachial artery.—The PRESIDENT suggested that the condition might be due to *B. diphtheriae*, and remembered two somewhat similar cases where diphtheroids had been isolated.

Mr. BRENNAN DYBALL showed a skiagram of a case of anterior spina bifida in the upper dorsal region in a girl aged 15. Nothing abnormal had been noticed until one year ago when the parents remarked that she had become round-shouldered. Examination showed well-marked kyphosis with considerable rigidity in the upper dorsal and cervical regions and with a slight lateral curve convex to the left. The situation of the curve suggested that the case was not one of ordinary scoliosis and the skiagram revealed the true nature.

Dr. R. MICHELMORE read notes and showed tumour removed post mortem from a case of cystic glioma in a man aged 63. The man had first complained of pain in the abdomen, constipation, and tired feeling in September, 1927. A month later there followed left facial paresis of upper motor neuron type and the left pupil was found to be larger than the right. Shortly afterwards difficulty in gait was prominent and mental deterioration showed itself. Examined on Nov. 5th, 1928, the paresis of the face was more marked and the left arm was not raised unless he was urged to do so—there was also bilateral optic neuritis and loss of sphincteric control. The Wassermann reaction was negative. Post mortem a cyst, 3 inches in diameter, was removed from the left temporal region of the brain.

Dr. F. A. ROPER showed cases of bilateral lumbar tumour and encephalitis; Dr. MILLER showed a boy suffering from acute rheumatism; Dr. C. N. LOVELY demonstrated xanthoma multiplex; Dr. ROY CRAIG showed cases of Hodgkin's disease and amyotrophic lateral sclerosis; and Mr. WAYLAND SMITH a case of head injury.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Nov. 7th, with Dr. R. W. MARSDEN, the President, in the chair. A paper on

Convulsions in Children

was read by Dr. C. PAGET LAPAGE, who divided the causes of convulsions into the following three classes:—

1. (a) Acute infections such as encephalitis, encephalitis lethargica, and meningitis. (b) Mechanical such as birth injury, or haemorrhage with hemiplegia or diplegia; malformation as porencephaly, microcephaly; cerebral tumour, cortical (may be localised); cerebellar tumour, cerebral abscess, whooping-cough with haemorrhage, cerebral injury.

2. Metabolic and toxic. Nerve endowment, normal or abnormal. (a) Rickets with peripheral irritation or additional metabolic upset (gastro-intestinal, bronchial, acute infection). (b) Tetany and spasmophilia with calcium deficiency; parathyroid deficiency (may be with rickets); (increased electrical reactions, Chrostek's sign, Trousseau's sign, crowing spasm, carpo-pedal spasm); some acute and some periodical. (c) Simple overfeeding, especially if rickets or tetany or nervous diathesis; worms. (d) Severe metabolic upsets as uremia, hypoglycaemia, anaphylaxis, onset of acute illness, &c.

3. Epilepsy. (a) Idiopathic, (b) accidental. Hereditary endowment of unstable nervous system. Family history of neuropathic disorders. Might be called functional, but of neuropathic or toxic disorders as well. Overstrain and usually metabolic or toxic disorders as well. Grand mal; petit mal. Isolated or only in first few years of life. Occasional, with congenital heart; idiopathic of infancy (Thomson); hysteria and hystero-epilepsy.

Dr. Lapage said that if convulsions were correctly placed under these headings prognosis and treatment were very much simplified. The importance of signs of spasmophilia, especially Chrostek's sign, was great, because if they were present there was considerable hope that the cause was spasmophilia and not one of the less tractable conditions. Naturally, if the case was due to spasmophilia the hope of cure was much greater, because spasmophilia was due to

some alteration of metabolism usually amenable to treatment. Continued fits in children were often due to an attack of polio-encephalitis which left an irritable area in the brain. As a result of increasing experience, he felt that more and more cases, which would formerly have been put under the class "epilepsy," should really be placed in the class "organic convulsions caused by some brain lesion." Polio-encephalitis was much commoner than was usually supposed. Attacks simulating petit mal must first of all be distinguished from pyknolepsy, a condition in which the prognosis was quite good, and in which there were very large numbers of small "absences" but never real fits; and also they must be distinguished from attacks like petit mal which occurred in cerebral lesions, especially cerebral or cerebellar tumours. Precursors of Jacksonian epilepsy might be the sudden momentary attacks which caused the child to fall down either backwards or forwards. Cerebral surgery in these cases was often disappointing, but it must always be remembered that hydatid of the brain, even in young children, was not unknown. The possibility of a specific origin must also be remembered and a Wassermann reaction taken.

In the treatment of epilepsy, Dr. Lapage emphasised the value of luminal and the need for careful supervision of diet and daily habits. He reported a case of successful control of fits by a ketonic diet.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting of this Institution on Nov. 15th Dr. C. O. STALLYBRASS read a paper on

Naturally Acquired Immunity in Human Communities.

In outlining the history of our knowledge of acquired immunity, he pointed out that deductions from laboratory experiments were not always applicable to man, owing to different portals of infection and the greater longevity among human beings. The effectiveness and the rate at which acquired immunity was lost in different diseases could be gauged by the liability to relapses and second attacks. A very high and permanent immunity was often secured in diseases caused by filterable viruses; in the bacterial diseases it tended to be less; in the protozoal and spirochaetal diseases the immunity was often of a very low order—e.g., in relapsing fever and malaria. Much light had been thrown upon the rate of loss of immunity in man by the steady increase both in the numbers of lesions and of fatality in severe small-pox with the lapse of time since vaccination was performed. Infection might produce the typical clinical cases, the abortive cases, the *formes frustres*, and the subinfections. This latter term had been applied by Adams in 1899 to the passage of intestinal organisms during digestion and in inflammatory states of the intestine, into the lymph channels and the portal system. Each of these types of infection might be effective in producing immunity.

The results acquired from the use of the tests for susceptibility to toxins (Boerner, Schick, Dick), and of cutaneous hypersensitiveness (Zeller, Pirquet, type skin), and for the presence of agglutinins (Widal, Weil-Felix) had thrown much light on the acquisition of immunity both in the individual and the herd. They indicated a much wider spread of infection or infection than was shown by the statistics of typical diseases. Although the visible epidemic of the influenza epidemic there was an invisible epidemic of subinfection, revealed only by bacteriological tests or the immunity reactions just described, and the visible epidemic was, in a number of diseases, more effective in the production of herd immunity than was the visible epidemic. Dr. Stallybrass gave examples from the typhoid, and from the paratyphoid infections, from typhus fever, and from poliomyelitis, in all of which the *formes frustres* and the subinfecting sub-

infections occurred with greater or less invisible frequency. In poliomyelitis there was evidence that a most extensive invisible epidemic accompanied the visible outbreak and left behind it a highly immune population. In other diseases, such as small-pox and measles, the subinfections played little or no part in producing herd immunity. The converse aspect of the case was the doctrine stated by Dudley that those who had been longest exposed to an infected environment suffered least when exposed to an epidemic and those who had been least exposed suffered most.

New Inventions.

A TONSIL ECRASEUR.

THE illustration shows an ecraseur with two rings, one of which fits within the other. When the instrument is manipulated into the lumen and put into action these rings press concentrically upon the structures around the tonsil and thereby crush them. The closure is first made by slow pressure of the thumb. When the tonsil is well gripped it is continued

The tonsil ecraseur.

still more slowly by the action of a screw. The flat bands of steel are quite blunt. The outer is split in order to receive the inner. There is nothing original in the instrument.

It merely combines the advantages of previous ones; the handle is that of Sluder's guillotine; but any handle can be mounted to it, and Mr. T. B. Jobson uses a very similar instrument with a grip handle. The arrangement of the rings is similar to that in Fahnstock's guillotine. The knife has been replaced by a flat band as in Meding's instrument. I have adapted to the outer ring a valuable modification devised by Sir James Dundas-Grant. The ring in section is not circular but rectangular. This gives a better purchase to the posterior border of the tonsil than does a rounded margin, and many tonsils can thereby be delivered into the ring that would otherwise need dissection. The instrument has now been in use for over two years, and I can say with confidence that it enucleates the tonsils as completely and more cleanly than does any method by dissection. Moreover, it does this without any loss of blood. No sucker is needed and no sponge is used. It is not claimed that this instrument is incapable of improvement. The fact that the terminal portions with the rings are detachable makes it possible to experiment with new rings and minor modifications at a low cost. It is, however, claimed that instruments such as these will make the operation of dissection of tonsils under general anaesthesia a thing of the past except under the rarest of circumstances.

I have to thank Messrs Down Bros, of St. Thomas's street, S.E., for their unfailing courtesy in the construction of the instrument.

T. B. LAYTON, M.B., M.S. Lond., F.R.C.S. Eng.

ANOTHER HOSPITAL.—A month ago the Board of the Manchester Hospital made their customary appeal for financial aid to the public, and in the meantime the operating theatre and the laboratory and the experimental department. Up to date they have received £1,000.

Dr. H. A. ELLIS said it was always important to examine the condition of the urine in these cases, especially as to its specific gravity. If the urine was of high concentration the pain would not be got rid of until the urine was put right. If the case was one of osteo-arthritis one could be sure of the diagnosis if the urine was of high specific gravity. In both types—high and low gravity urine—there might be an excess of uric acid.

Dr. WILFRED HARRIS, in reply, thanked Dr. Brailsford for his excellent series of skiagrams. He asked Mr. Verrall what were his views on the use of anaesthetics when doing manipulations. Some people preferred to do manipulations without giving a general anaesthetic.

Mr. VERRALL, in reply, said he thought it impossible to do manipulation of the sacro-iliac joint or spine without using a general anaesthetic. He gave a demonstration of his method of carrying it out.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this Society was held on Nov. 22nd, with Mr. A. L. CANDLER, the President, in the chair.

Dr. C. H. MILLER showed a man, aged 54, with splenomegaly, anaemia, and gout.

The patient gave a history of gout dating back several years, and he had lost weight recently. There was no vomiting and no loss of appetite. In September, 1928, he first noticed pain immediately after dinner, this lasted several days and then began to subside. The family history was good and the man could not remember any serious illness.

The chief points of interest in the case were (1) the general colour, (2) the tophi on the pinnae, (3) splenomegaly, and (4) enlarged glands in the groins and elsewhere. A blood count on Sept. 20th, 1928, showed haemoglobin, 22 per cent.; red cells, 1,910,000; and white cells, 10,400. Differential count: polymorphs, 60 per cent.; lymphocytes, 34 per cent.; large mononuclears, 5 per cent.; eosinophils, nil; and mast cells, 1 per cent.

There was slight variation, said Dr. Miller, in the size and shape of the red cells, but no nucleated cells were seen. The Wassermann reaction was negative. Four weeks after admission a further blood estimation showed a slight rise in haemoglobin and an increase in the number of red cells to 4,060,000. The leucocytes now totalled 8400, with a differential count within normal limits. Stimulated by the results obtained with liver in a case of pernicious anaemia in the neighbouring bed, he had given it a trial here also, but with no advantage. More good seemed to be referable to chlorophyll-carrying agents and atophan.—Dr. R. V. SOLLY had found it impossible to classify the affection from the point of view of the blood picture.—Dr. T. R. WHIPHAM remarked upon the persisting low figure of the haemoglobin in the second count and also upon the absence of any nucleated red cells as evidence of the blood regeneration which might be presumed to have taken place on comparing the two counts.

Mr. R. WAYLAND SMITH showed a woman, aged 29, suffering from superficial gangrene of the skin following a burn. Some 18 months ago she had burnt her thumb and this continued to suppurate, in spite of energetic treatment, and eventually reached a condition of dry gangrene necessitating amputation of the thumb in July of this year. Since then she had developed patches of superficial gangrene on the wrist and hand of the same side. No sugar had been detected in the urine or other cause discovered for this obstinate condition. *Staphylococcus aureus* was isolated from the pus and vaccines so obtained alone isolated from the pus and vaccines so obtained were worked up to 700 millions. Locally Mr. Wayland Smith had tried dichloramine dressings and ultra-violet rays. He invited the opinion of the meeting as to diagnosis and treatment.—Mr. NORMAN LOCK suggested the possibility of scleroderma and, all other

means failing, the thectomy of the suggested that *B. diphtheriae*, and cases where diphth

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society with Dr. R. W. MARSDEN, the A paper on

Convulsions in

was read by Dr. C. PAGET the causes of convulsions into classes:—

1. (a) Acute infections such as encephalitis, and meningitis. (b) Mechanical injury, or haemorrhage with hemiplegia, or formation as porencephaly, microcephaly, cortical (may be localised); cerebral abscess, whooping-cough with haemorrhage.
2. Metabolic and toxic. Nerve end abnormal. (a) Rickets with peripheral metabolic upset (gastro-intestinal, bronchial) (b) Tetany and spasmodophilia with parathyroid deficiency (may be with electrical reactions, Chvostek's sign, crowing spasm, carpo-pedal spasm); some periodical. (c) Simple overfeeding, especially tetany or nervous diathesis; worms. (d) upsets as uraemia, hypoglycaemia, anaphylaxis, acute illness, &c.

3. Epilepsy. (a) Idiopathic, (b) accident endowment of unstable nervous system. of neuropathic disorders. Might be called usually metabolic or toxic disorders as well. toxins. Nerve-cells irritated. Grand mal Isolated or only in first few years of life. Occ congenital heart; idiopathic of infancy (Thomson) and hystero-epilepsy.

Dr. Lapage said that if convulsions were placed under these headings prognosis and were very much simplified. The importance of spasmodophilia, especially Chvostek's sign, was great, because if they were present there was considerable hope that the cause was spasmodophilia, not one of the less tractable conditions. No if the case was due to spasmodophilia the hope was much greater, because spasmodophilia was

some alteration of metabolism usually amenable to treatment. Continued fits in children were often due to an attack of polio-encephalitis which left an irritable area in the brain. As a result of increasing experience, he felt that more and more cases, which would formerly have been put under the class "epilepsy," should really be placed in the class "organic convulsions caused by some brain lesion." Polio-encephalitis was much commoner than was usually supposed. Attacks simulating petit mal must first of all be distinguished from pyknolepsy, a condition in which the prognosis was quite good, and in which there were very large numbers of small "absences" but never real fits; and also they must be distinguished from attacks like petit mal which occurred in cerebral lesions, especially cerebral or cerebellar tumours. Precursors of Jacksonian epilepsy might be the sudden momentary attacks which caused the child to fall down either backwards or forwards. Cerebral surgery in these cases was often disappointing, but it must always be remembered that hydatid of the brain, even in young children, was not unknown. The possibility of a specific origin must also be remembered and a Wassermann reaction taken.

In the treatment of epilepsy, Dr. Lapage emphasised the value of luminal and the need for careful supervision of diet and daily habits. He reported a case of successful control of fits by a ketonic diet.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting of this Institution on Nov. 15th Dr. C. O. STALLYBRASS read a paper on

Naturally Acquired Immunity in Human Communities.

In outlining the history of our knowledge of acquired immunity, he pointed out that deductions from laboratory experiments were not always applicable to man, owing to different portals of infection and the greater longevity among human beings. The effectiveness and the rate at which acquired immunity was lost in different diseases could be gauged by the liability to relapses and second attacks. A very high and permanent immunity was often secured in diseases caused by filterable viruses; in the bacterial diseases it tended to be less; in the protozoal and spirochaetal diseases the immunity was often of a very low order—e.g., in relapsing fever and malaria. Much light had been thrown upon the rate of loss of immunity in man by the steady increase both in the numbers of lesions and of fatality in severe small-pox with the lapse of time since vaccination was performed. Infection might produce the typical clinical cases, the abortive cases, the *formes frustes*, and the subinfections. This latter term had been applied by Adami in 1899 to the passage of intestinal organisms during digestion and in inflammatory states of the intestines, into the lymph channels and the portal system. Each of these types of infection might be effective in producing immunity.

The results acquired from the use of the tests for susceptibility to toxins (Romer, Schick, Dick), and of cutaneous hypersensitiveness (Zoller, Pirquet, typhoidin), and for the presence of agglutinins (Widal, West-Edel) had thrown much light on the acquisition of immunity both in the individual and the herd. They indicated a much wider spread of infection or subinfection than was shown by the statistics of notifiable diseases. Alongside the visible epidemic of clinically diagnosed cases there was an invisible epidemic of subinfections, revealed only by bacteriological tests or the immunity reactions just described, and the invisible epidemic was, in a number of diseases, more effective in the production of herd immunity than was the visible epidemic. Dr. Stallybrass quoted examples from the typhoid, and more especially the paratyphoid infections, from typhus, from cholera, and from poliomyelitis. In all of these the *formes frustes* and the immunising sub-

infections occurred with greater or less invisible frequency. In poliomyelitis there was evidence that a most extensive invisible epidemic accompanied the visible outbreak and left behind it a highly immune population. In other diseases, such as small-pox and measles, the subinfections played little or no part in producing herd immunity. The converse aspect of the case was the doctrine stated by Dudley that those who had been longest exposed to an infected environment suffered least when exposed to an epidemic and those who had been least exposed suffered most.

New Inventions.

A TONSIL ECRASEUR.

THE illustration shows an ecraseur with two rings, one of which fits within the other. When the instrument is manipulated into the lumen and put into action these rings press concentrically upon the structures around the tonsil and thereby crush them. The closure is first made by slow pressure of the thumb. When the tonsil is well gripped it is continued

The tonsil ecraseur.

still more slowly by the action of a screw. The flat bands of steel are quite blunt. The outer is split in order to receive the inner. There is nothing original in the instrument.

It merely combines the advantages of previous ones; the handle is that of Sluder's guillotine; but any handle can be mounted to it, and Mr. T. B. Jobson uses a very similar instrument with a grip handle. The arrangement of the rings is similar to that in Fahnstock's guillotine. The knife has been replaced by a flat band as in Meding's instrument. I have adapted to the outer ring a valuable modification devised by Sir James Dundas-Grant. The ring in section is not circular but rectangular. This gives a better purchase to the posterior border of the tonsil than does a rounded margin, and many tonsils can thereby be delivered into the ring that would otherwise need dissection. The instrument has now been in use for over two years, and I can say with confidence that it enucleates the tonsils as completely and more cleanly than does any method by dissection. Moreover, it does this without any loss of blood. No sucker is needed and no sponge is used. It is not claimed that this instrument is incapable of improvement. The fact that the terminal portions with the rings are detachable makes it possible to experiment with new rings and minor modifications at a low cost. It is, however, claimed that instruments such as these will make the operation of dissection of tonsils under general anaesthesia a thing of the past except under the rarest of circumstances.

I have to thank Messrs Down Bros. of St. Thomas's-street, S.E., for their unfailing courtesy in the construction of the instrument.

T. B. LAYTON, M.B., M.S. Lond., F.R.C.S. Eng.

ANCOATS HOSPITAL.—A month ago the board of this Manchester hospital made their centenary appeal for £100,000 to enable them to add 100 beds and run additional operating theatres and to enlarge various overcrowded departments. Up to date they have received £26,000.

Reviews and Notices of Books.

ESSENTIALS OF MEDICAL DIAGNOSIS.

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P., and A. E. GOW, M.D., F.R.C.P. London: Cassell and Company. 1928. Pp. 682. 16s.

IN this book a successful attempt is made to relay the foundation-stones of the art of diagnosis. Its outlook is consistent and the material put before the reader is admirably condensed. Few, if any, medical facts are omitted; nothing which is not a fact is included; in short, the book deals with diagnosis and not with hypotheses of disease. A notable feature in every section is the physiological epitome that precedes the clinical discussion. The preliminary survey of the central nervous system in Section I., the account of the blood in Section VII., the short description of the normal secretion of bile in Section V., and the introduction to Section VI., which deals with the urinary system, are inimitable. On the clinical side all kinds of examination are dealt with, from history-taking and the simple methods of inspection and palpation, to the more specialised technique of the electrocardiogram, radiography with lipiodol, fractional test-meals, estimation of the blood-urea, van den Bergh's tests, and so forth, these being set out not indeed in great detail but with respect to their exact bearing on diagnosis. Numerous plates, diagrams, charts, and radiograms illustrate the text. Variations in different diseases of the excreta, urine, sputum, and faeces are well described. In the section on the cardiovascular system the authors consider that the position of the apex-beat of the heart should be stated in reference to the nipple line, holding that measurement from the mid-femoral line "is of no value between one case and another, seeing that the criteria vary with age, build, and sex."

This book will appeal to students and practitioners who are anxious to base their medical knowledge upon scientific rather than upon hypothetical considerations. In it they will find a refreshing variety of reading, facts old and new, and a poise which will help them when they are confronted with a case difficult to diagnose.

GYNECOLOGY.

Les troubles fonctionnels de l'appareil génital de la femme. Étude physiologique, clinique et thérapeutique. By GASTON COTTE, Professeur Agrégé à la Faculté de Médecine de Lyon; Chirurgien des Hôpitaux. Paris: Masson et Cie. 1928. Pp. 570. Fr.60.

THE author is a profound disbeliever in the habit, too common among gynaecologists, of labelling as "functional" various gynaecological symptoms of obscure or unknown origin. In this book he has attempted to search out the underlying pathological conditions in such cases. He does not always succeed, but his attempt is a praiseworthy one, because he brings unsolved problems into the foreground, and voices a wholesome scorn of the frame of mind that can rest satisfied with anything less than accurate diagnosis based upon carefully observed pathological and anatomical data. The first 200 pages of the book are occupied with menstruation and its disorders. A good account of the menstrual cycle in lower mammals is followed by a description of that in human females, normal and pathological. The rôle of ovarian disease, especially sclero-cystic disease of the ovary, in the causation of polymenorrhœa or epimenorrhœa, and of metrorrhagia, is emphasised, and an excellent and comprehensive account is given of the work of continental workers. This section is particularly suggestive, for it is tempting to seek for mechanical or local uterine explanations for these disorders, and if these cannot be found, to label the

menstrual abnormality as "functional" or "essential." The author does not confine himself to purely "functional" lesions; in a long section on sterility, occupying almost 100 pages, organic closure of the tubes is fully dealt with. The use of lipiodol is favoured in diagnosis, and a special method is described of guarding against reflux through the cervix during injection. A mercury manometer is used to indicate the pressure at which injection is taking place, 120-150 mm. being usually necessary in normal cases. In suitable cases implantation of the tubes into the uterus is advocated, and even implantation of the ovaries according to the method of d'Estes and Tuffier, and it is stated that these operations have already been justified by results. Sterility may be due to sclero-cystic disease of the ovaries, and may be successfully treated by resection or enucleation of the cysts. Other chapters deal with circulatory disturbances of the genital organs, their nerve-supply and nervous disturbances, dysmenorrhœa, ovarian insufficiency, disturbances following castration, and so forth.

The book is a valuable and laborious contribution to a difficult subject, to which, judging from the numerous references to the work of French and German authors, more attention has been paid on the Continent than in this country or in America.

PSYCHOLOGY.

Instinct and Personality. By A. CAMPBELL GARNETT, M.A., Litt.D., University of Adelaide. London: George Allen and Unwin, Ltd. 1928. Pp. 218. 8s. 6d.

ON the basis of the inadequacy of physical energy to explain the mental life of the organism, Dr. Garnett establishes his thesis upon the pre-eminence of mind. The views of the early part of the book are familiar to those who are conversant with the psychology of J. Stout and W. McDougall, and show that instinct and the phenomena of expectation are inexplicable in the absence of mind. Of particular interest to medicine are the chapters on Expectation, where Coué's work receives appreciative comment, and the Explanation of the Unconscious. In this chapter the Freudian conception is very thoroughly analysed. The author concludes that a *mental* unconscious does not exist, that the processes here are entirely physiological and that the phenomena giving rise to the symptoms in neurosis are better explained by suggestion and dissociation. Mr. Garnett argues that the phenomena of dissociation are entirely in favour of the unitary activity of the organism expressing itself through the mind, and that therefore without the concept of personality we possess no system of reference. Teleology is the mainspring of human activity and instincts are the agency for the expression of the total personal trend. In the body-mind relationship we see the work of mind in using physical energy as its instrument. Consciousness becomes not merely "the growing point of life, but the growing point of the universe." A thoughtful book, well worth reading.

Judgement and Reasoning in the Child. By JEAN PIAGET, Professor at the University of Geneva; International Library of Psychology and Scientific Method. London: Kegan Paul, Trench, Trübner and Co. 1928. Pp. 260. 10s. 6d.

NO one engaged in education, in mental testing, or in the treatment of the behaviour disorders of a childhood can afford to ignore this book, which is a continuation of the author's earlier work, "Language and Thought of the Child." Having established the ego-centric thought processes of the child, Prof. Piaget carries out an extensive research and acute analysis of the logic used by children in facing propositions denoting causality and relationship. To describe the evolution of thought from the purely biological and sociological points of view is to risk casting in the shade half of the real process. Between the ego-centric

life of the child—the realm of pure imagination—and the period of verification lies all the difference between Freud's pleasure principle and the reality principle. The latter is truly the realm of logic. It is the shock of contact with an external world of obstinate fact that calls out in the child the need for verification. The greater part of this book is an application of the Binet-Simon tests to the problem of logical development and calls for careful study; this will be amply repaid by a new insight into the process of the child mind.

The publishers deserve gratitude for the excellent translation of this and the earlier treatise, both of which are rich additions to psychological literature.

The Philosophic Bases of Education. By ROBERT R. RUSK, M.A., B.A. Camb., Ph.D., Principal Lecturer in Education, Glasgow Teachers Training Committee. London: University of London Press, 1928. Pp. 205. 5s.

Mr. Rusk's object in this volume is to examine the various philosophic standpoints which have been taken up by writers on education, to demonstrate their value in themselves, and to assess their value as applied to educational theory. He indicts naturalism in psychology because it is retrospective and introduces a fatalism into mental tests which throws no light on conscience and the highest human aspirations. Pragmatism, too, fails, since it does not encourage a disinterested love of knowledge. Only in idealism can we find a satisfactory basis for educational theory and practice. It is a matter of some interest that the author finds in psycho-analysis an implicit recognition of the moral order when it lays emphasis on the mechanism of conflict in shaping behaviour. It is the notion of conflict that runs through all educational efforts. The best educational method is that which resolves conflicts between instinctive tendencies and social ends in the interest of the latter.

This book was well worth writing, and in the welter of nihilism in present-day thinking it is encouraging to find a writer who emphasises the importance of values in applied psychology.

DIFFERENTIAL-DIAGNOSTIK INNERER KRANKHEITEN.

By Prof. Dr. NORBERT ORTNER, Vorstand der II med. Klinik der Universität, Wien. Berlin and Vienna: Urban und Schwarzenberg, 1928. Pp. 827. M.30.

This is a first-class book, whose author claims that he has considered only those conditions the differential diagnosis of which is neglected in ordinary books. There are 73 sections, including such subjects as pneumothorax, ascites, epigastric tumours, polyuria, and Addison's disease. The chapters are rich in clinical detail, and the impression given is that of careful and experienced bedside observation. The thorough treatment of a subject can be judged from the fact that under "gastric ulcer" the following subdivisions are given: chronic gastritis, phlegmonous gastritis, haemorrhagic erosions, hyperacidity, hypersecretion, achylia, mucous gastritis, gall-stones, appendicitis, hernia of the linea alba, femoral hernia, inguinal hernia, diaphragmatic hernia, gastric crises, duodenal ulcer, malaria, abdominal aneurysm, radiocutis, cancer of spine, secondary growth in spine, typhoid, pharynx, pneumothorax, intestinal colic, intestinal parasites, scar of gastric ulcer, adhesive peritonitis, chronic lead poisoning, nervous gastritis, enteroptosis, pulmonary tuberculosis, and carcinoma of stomach. In haemorrhagic gastric ulcer the pain is described as severe, and as continuing till the third quarter of an hour after food with irradiation or associated hyperæsthesia. It is stated that after one week of rest the ulcer is self-healing.

The sections in which a single symptom or sign is discussed in all its bearings are excellent. For

example, the differential diagnosis of obesity distinguishes between the forms due to dietetic causes, myxœdema, adrenal cortical tumour, pituitary or pineal dysfunction, the climacteric and Dercum's disease. Other symptoms are treated no less exhaustively. This volume should be of considerable use to the teacher and consultant in solving difficult cases.

CLINICAL ELECTROCARDIOGRAPHY.

Fourth edition. By Sir THOMAS LEWIS, M.D., F.R.S., D.Sc., F.R.C.P., C.B.E. London: Shaw and Sons, Ltd. 1928. Pp. 128. 8s. 6d.

It is no longer possible for the general physician to be an expert in all departments of medicine; but it is not unreasonable to expect at any rate those at the head of their profession to be conversant with the scope and general principles of modern laboratory methods of diagnosis. Of such methods electrocardiography is one of the most technical; but as Sir Thomas Lewis says in the new edition of this book, "cases of structural heart disease are few in which an electrical examination is superfluous, and in a not inconsiderable percentage of cases the records modify, more or less profoundly, our conception of the malady that we treat." The opening chapter alone is devoted to technique, while in the remainder of the book the author deals with the normal electrocardiogram and the various modifications which it exhibits under pathological conditions. This edition includes a summary of the important recent work on the electrocardiographic findings in thrombosis of the coronary arteries. It is surprising what a fund of information has been condensed into so small a space, yet unlike many small books on technical subjects, this one is easy and fascinating to read. This is due partly to the carefully chosen collection of beautiful records, and partly to the clear thinking and exceptional descriptive powers which we are accustomed to associate with the writings of Sir Thomas Lewis. To the general physician and to all those who wish to keep abreast of the times in cardiology, this book will be invaluable; it contains the essentials of the subject in an easily assimilable form.

MECHANICS OF THE DIGESTIVE TRACT.

Second edition. By WALTER C. ALVAREZ, M.D., Associate Professor of Medicine, University of Minnesota. London: William Heinemann, Ltd. 1928. Pp. 117. 31s. 6d.

Dr. Alvarez's book first appeared in 1921 and was immediately recognised as a work of great importance by all those especially interested in the mechanics of the alimentary canal. At the time of its publication the author was working in San Francisco. He is now associated with the Mayo Foundation and acknowledges in the preface to the present edition the enhanced facilities for research which have come to him with this appointment. The medical public also benefits from these facilities, for they are now supplied with a vast amount of data collected by a man of studious and original mind who has devoted his life to the problems of intestinal movements. Dr. Alvarez has not only pursued research by unceasing experiment, but has also made a continuous study of the radiographic appearances of the living bowel; his work has thus a clinical value seldom found in the publications of purely laboratory workers. On such problems as the production of cardiospasm, congenital pyloric stenosis, megacolon, or the genesis of flatulence, his opinion will be noted with deep respect even by those who may not agree with his conclusions. The book is profusely illustrated by diagrams and photographs, including many portraits of eminent workers, both alive and dead.

The author has evidently been able to find inspiration even in the work of his opponents and it is certain that his book in its turn will provide widespread interest and discussion.

Reviews and Notices of Books.

ESSENTIALS OF MEDICAL DIAGNOSIS.

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D.
F.R.C.P., and A. E. GOW, M.D., F.R.C.P. London:
Cassell and Company. 1928. Pp. 682. 16s.

In this book a successful attempt is made to relay the foundation-stones of the art of diagnosis. Its outlook is consistent and the material put before the reader is admirably condensed. Few, if any, medical facts are omitted; nothing which is not a fact is included; in short, the book deals with diagnosis and not with hypotheses of disease. A notable feature in every section is the physiological epitome that precedes the clinical discussion. The preliminary survey of the central nervous system in Section I., the account of the blood in Section V., the short description of the normal secretion of bile in Section V., and the introduction to Section VI. which deals with the urinary system, are inimitable. On the clinical side all kinds of examination are dealt with, from history-taking and the simple methods of inspection and palpation, to the more specialised technique of the electrocardiogram, radiography with lipiodol, fractional test-meals, estimation of the blood urea, van den Bergh's tests, and so forth, these being set out not indeed in great detail but with respect to their exact bearing on diagnosis. Numerous plates, diagrams, charts, and radiograms illustrate the text. Variations in different diseases of the excreta, urine, sputum, and feces are well described. In the section on the cardiovascular system the authors consider that the position of the apex-beat of the heart should be stated in reference to the nipple line, holding that measurement from the mid-sternal line "is of no value between one case and another, seeing that the criteria vary with age, build, and sex."

This book will appeal to students and practitioners who are anxious to base their medical knowledge upon scientific rather than upon hypothetical considerations. In it they will find a refreshing variety of reading, facts old and new, and a poise which will help them when they are confronted with a case difficult to diagnose.

GYNÆCOLOGY.

Les troubles fonctionnels de l'appareil génital de la femme. Étude physiologique, clinique et thérapeutique. By GASTON COTTE, Professeur Agrégé à la Faculté de Médecine de Lyon; Chirurgien des Hôpitaux. Paris: Masson et Cie. 1928. Pp. 570. Fr.60.

THE author is a profound disbeliever in the habit, too common among gynæcologists, of labelling as "functional" various gynæcological symptoms of obscure or unknown origin. In this book he has attempted to search out the underlying pathological conditions in such cases. He does not always succeed, but his attempt is a praiseworthy one, because he brings unsolved problems into the foreground, and voices a wholesome scorn of the frame of mind that can rest satisfied with anything less than accurate diagnosis based upon carefully observed pathological and anatomical data. The first 200 pages of the book are occupied with menstruation and its disorders. A good account of the menstrual cycle in lower mammals is followed by a description of that in human females, normal and pathological. The rôle of ovarian disease, especially sclero-cystic disease of the ovary, in the causation of polymenorrhœa or epimenorrhœa, and of metrorrhagia, is emphasised, and an excellent and comprehensive account is given of the work of continental workers. This section is particularly suggestive, for it is tempting to seek for mechanical or local uterine explanations for these disorders, and if these cannot be found, to label the

reading.

Judgement and Reason.
PIAGET, Professor.
International Library
Method. London: K
and Co. 1928. Pp. 2

No one engaged in education or in the treatment of the childhood can afford to ignore the continuation of the author's earlier work, *Child's Conception of the World*, and *Thought of the Child*. Having an ego-centric thought processes of Piaget carries out an extensive re-analysis of the logic used by children in their relations denoting causality and relationships. The evolution of thought from the purely mechanical and sociological points of view is to risk shade half of the real process. Between

life of the child—the realm of pure imagination—and the period of verification lies all the difference between Freud's pleasure principle and the reality principle. The latter is truly the realm of logic. It is the shock of contact with an external world of obstinate fact that calls out in the child the need for verification. The greater part of this book is an application of the Binet-Simon tests to the problem of logical development and calls for careful study; this will be amply repaid by a new insight into the process of the child mind.

The publishers deserve gratitude for the excellent translation of this and the earlier treatise, both of which are rich additions to psychological literature.

The Philosophic Bases of Education. By ROBERT R. RUSK, M.A., B.A. Camb., Ph.D., Principal Lecturer in Education, Glasgow Teachers Training Committee. London: University of London Press. 1928. Pp. 205. 5s.

Mr. Rusk's object in this volume is to examine the various philosophic standpoints which have been taken up by writers on education, to demonstrate their value in themselves, and to assess their value as applied to educational theory. He indicts naturalism in psychology because it is retrospective and introduces a fatalism into mental tests which throws no light on conscience and the highest human aspirations. Pragmatism, too, fails, since it does not encourage a disinterested love of knowledge. Only in idealism can we find a satisfactory basis for educational theory and practice. It is a matter of some interest that the author finds in psycho-analysis an implicit recognition of the moral order when it lays emphasis on the mechanism of conflict in shaping behaviour. It is the notion of conflict that runs through all educational efforts. The best educational method is that which resolves conflicts between instinctive tendencies and social ends in the interest of the latter.

This book was well worth writing, and in the welter of nihilism in present-day thinking it is encouraging to find a writer who emphasises the importance of values in applied psychology.

DIFFERENTIAL-DIAGNOSTIK INNERER KRANKHEITEN.

By Prof. Dr. NORBERT ORTNER, Vorstand der II. med. Klinik der Universität, Wien. Berlin and Vienna: Urban und Schwarzenberg. 1928. Pp. 827. M.30.

THIS is a first-class book, whose author claims that he has considered only those conditions the differential diagnosis of which is neglected in ordinary books. There are 73 sections, including such subjects as pneumothorax, ascites, epigastric tumours, polyuria, and Addison's disease. The chapters are rich in clinical detail, and the impression given is that of careful and experienced bedside observation. The thorough treatment of a subject can be judged from the fact that under "gastric ulcer" the following subdivisions are given: chronic gastritis, phlegmonous gastritis, hemorrhagic erosions, hyperacidity, hypersecretion, achylia, mucous gastritis, gall-stones, appendicitis, hernia of the linea alba, femoral hernia, inguinal hernia, diaphragmatic hernia, gastric crises, duodenal ulcer, malaria, abdominal aneurysm, radiculitis, caries of spine, secondary growth in spine, spondylitis, pleurisy, pneumothorax, intestinal colic, intestinal parasites, scar of gastric ulcer, adhesive typhilitis, chronic lead poisoning, nervous gastritis, enteroptosis, pulmonary tuberculosis, and carcinoma of stomach. In hemorrhagic gastric crises the pain is described as severe, and as continuing half to three-quarters of an hour after food without radiation or associated hyperæsthesia. It is stated that after one week of milk diet the symptoms and signs disappear.

The text, as in which a single symptom or sign is discussed in all its bearings, are excellent. For

example, the differential diagnosis of obesity distinguishes between the forms due to dietetic causes, myxœdema, adrenal cortical tumour, pituitary or pineal dysfunction, the climacteric and Dercum's disease. Other symptoms are treated no less exhaustively. This volume should be of considerable use to the teacher and consultant in solving difficult cases.

CLINICAL ELECTROCARDIOGRAPHY.

Fourth edition. By Sir THOMAS LEWIS, M.D., F.R.S., D.Sc., F.R.C.P., C.B.E. London: Shaw and Sons, Ltd. 1928. Pp. 128. 8s. 6d.

It is no longer possible for the general physician to be an expert in all departments of medicine; but it is not unreasonable to expect at any rate those at the head of their profession to be conversant with the scope and general principles of modern laboratory methods of diagnosis. Of such methods electrocardiography is one of the most technical; but as Sir Thomas Lewis says in the new edition of this book, "cases of structural heart disease are few in which an electrical examination is superfluous, and in a not inconsiderable percentage of cases the records modify, more or less profoundly, our conception of the malady that we treat." The opening chapter alone is devoted to technique, while in the remainder of the book the author deals with the normal electrocardiogram and the various modifications which it exhibits under pathological conditions. This edition includes a summary of the important recent work on the electrocardiographic findings in thrombosis of the coronary arteries. It is surprising what a fund of information has been condensed into so small a space, yet unlike many small books on technical subjects, this one is easy and fascinating to read. This is due partly to the carefully chosen collection of beautiful records, and partly to the clear thinking and exceptional descriptive powers which we are accustomed to associate with the writings of Sir Thomas Lewis. To the general physician and to all those who wish to keep abreast of the times in cardiology, this book will be invaluable; it contains the essentials of the subject in an easily assimilable form.

MECHANICS OF THE DIGESTIVE TRACT.

Second edition. By WALTER C. ALVAREZ, M.D., Associate Professor of Medicine, University of Minnesota. London: William Heinemann, Ltd. 1928. Pp. 447. 31s. 6d.

Dr. Alvarez's book first appeared in 1921 and was immediately recognised as a work of great importance by all those especially interested in the mechanics of the alimentary canal. At the time of its publication the author was working in San Francisco. He is now associated with the Mayo Foundation and acknowledges in the preface to the present edition the enhanced facilities for research which have come to him with this appointment. The medical public also benefits from these facilities, for they are now supplied with a vast amount of data collected by a man of studious and original mind who has devoted his life to the problems of intestinal movements. Dr. Alvarez has not only pursued research by unceasing experiment, but has also made a continuous study of the radiographic appearances of the living bowel; his work has thus a clinical value seldom found in the publications of purely laboratory workers. On such problems as the production of cardiac-spasm, congenital pyloric stenosis, megacolon, or the genesis of flatulence, his opinion will be noted with deep respect even by those who may not agree with his conclusions. The book is profusely illustrated by diagrams and photographs, including many portraits of eminent workers, both alive and dead.

The author has evidently been able to find inspiration even in the work of his opponents and it is certain that his book in its turn will provoke widespread interest and discussion.

AN ATLAS OF OPHTHALMOSCOPY.

By Dr. O. HAAB, Professor of Ophthalmology, University of Zurich. Translated and edited by W. B. BARKER, F.B.O.A. (Hons.), Lecturer in Applied Optics, College of Technology, Manchester. London: British Optical Association. 1928. Pp. 230.

THE edition of Haab's Atlas best known to English readers is the American one edited by Prof. de Schweinitz, the second edition of which was published in 1909. In the present edition the text is retranslated with some additional matter concerning self-luminous instruments and red-free screens. The plates are reprinted from the original stones. The preface is addressed to opticians—presumably with the suggestion that they should be able to distinguish between diseased and a normal fundus. Although all the plates are good, and the usefulness of some of them has been increased by the addition of illustrations of microscopical sections of eyes suffering from the diseases pictured, several typical conditions both of normal and diseased fundi are omitted—for example, typical coloboma of the choroid and different varieties of physiological discs. On the other hand, one plate illustrates a condition so rare as to be a curiosity—a bubble of air in the vitreous. It is true that to illustrate all the different conditions of the fundus that one is liable to come across in practice would need not a book but a museum. Haab's Atlas

is excellent so far as it goes, but we are sure that the distinguished author would be the first to disclaim any idea that it is exhaustive.

A MANUAL OF HYGIENE AND PUBLIC HEALTH.

Second edition. By JAHAR LAL DAS, D.P.H., Officiating Assistant Director of Public Health, Bihar and Orissa. Calcutta: Butterworth and Co. (India), Ltd. 1928. Pp. 661. 6s.

THIS book has been brought up to date, increased in size by 27 pages, and reduced in price from 10s. 6d. to 6s. In its present form it gives quite remarkable value for this modest price. We are glad to note that some of the defects criticised in our review of the first edition have been removed, for instance, an attempt has been made to bring the references to bacterial food-poisoning up to date, and the term "ptomaine poisoning" has been dropped, but the author still uses the obsolete name of "B. suispestifer" in describing the bacterial causes of this disease. It is now universally accepted that the micro-organisms most definitely associated with food poisoning are *B. enteritidis* of Gaertner and *B. aertrycke*. The classification of rats is still imperfect and this is a matter of importance to all those concerned with the hygiene of Eastern countries. The book contains many illustrations, not all of equal merit, and a vast amount of clear and accurate information.

Reports and Analytical Records.

PLASMONA.

(PLASMON, LTD., 66A, FARRINGTON-STREET, LONDON, E.C.4.)

PLASMONA claims to be a blood and nerve food, and to contain the anti-anemic principle of liver combined with iron phosphatides, cerebrosides, cephalin, protagon, &c., the latter being constituents of the central nerve system, and the vitamin factors A, B, D, and E. The anti-anemic principle is derived from liver extract, vitamin A and B from liver substance and yeast, vitamin D from cod-liver oil extract, and vitamin E from wheat germ.

Plasmona is a pale, chocolate-coloured powder with a pleasant slightly sweet flavour.

On analysis the following results were obtained:—

Water	5.48 per cent.
Mineral matter	8.02 "
Protein	27.00 "
Sugars	34.60 "
Matter soluble in ether	8.38 "
Polysaccharides, tissue, and indeterminate matter	16.52 "

The mineral matter contained phosphates (P_2O_5) 0.3 per cent., and iron (Fe_2O_3) 0.35 per cent. Fifty-two per cent. of Plasmona is soluble in water and its reaction is neutral.

This is a food of a comprehensively planned character, and obviously contains all the necessary nutritional elements in a highly concentrated form. A portion of the iron and phosphorus is present in organic combination, thus aiding assimilation.

DIAMOND ALUMINIUM WARE.

(THE BRITISH ALUMINIUM CO., LTD., ADELAIDE HOUSE, KING WILLIAM-STREET, LONDON, E.C.4.)

For many years past the public has been interested in cooking vessels made of aluminium as this metal possesses so many advantages over iron or copper, and to-day they are in wellnigh universal use. From time to time statements have been made that traces of aluminium in foodstuffs are harmful, and the astounding allegation has been made that cancer may be attributable to food prepared in aluminium vessels. The results of an elaborate investigation dealing with the action of foodstuffs on aluminium appeared in our columns about 16 years ago (*THE LANCET*, 1913.

i., 54). The conclusion was reached that any suspicion of aluminium communicating poisonous qualities to food in the processes of cooking may safely be dismissed. Suspicion, however, endures, and whilst the harmlessness of metallic aluminium for cooking purposes has never been successfully challenged, we think it may not be out of place to record some fresh work we have carried out on the amount of aluminium taken up by water and meat when boiled and stewed under ordinary cooking conditions.

Water.—Ordinary London water containing about grs. 19 of saline matters per gallon, of which grs. 13 were calcium carbonate, was boiled for one hour in an aluminium kettle, and a similar volume in a glass beaker. The two waters were analysed, the one boiled in the kettle contained grs. 1.28 of aluminium per gallon, the other in glass gr. 0.01 per gallon. The water had thus dissolved grs. 1.27 of aluminium per gallon, or 0.00018 per cent. London water is, however, slightly alkaline, and as the kettle becomes "furred" the amount of aluminium dissolved will tend to become less.

Meat.—Fresh meat was gently boiled in tap water containing a little salt for one hour in an aluminium saucepan and in a glass vessel serving as a control. Analysis showed that no trace of aluminium had been dissolved from the metal vessel. This is a result which might have been anticipated from the work of J. A. N. Friend and R. H. Vallance (*Transactions Chem. Soc.*, 1921, cxxi., 932) and C. K. Tinkler and H. Masters (*Analyst*, 1924, xlix., 30), who found that the colloidal matter which is present in most foods materially lessens the amount of aluminium dissolved.

Although the published data on the toxicity of aluminium are very meagre, the general consensus of opinion appears to be that small quantities are without effect on the living organism. In some recent work of V. C. Myers, J. W. Mull, and D. B. Morrison (*Jour. Biol. Chem.*, 1928, lxxviii., 605), carried out on rats who received 2 mg. of aluminium per rat daily in addition to the stock diet, it was shown that the growth curves over four generations of these animals compared well with those of the controls. The aluminium-fed rats showed a slightly greater initial growth; in other respects the addition of aluminium to the diet was without effect.

It would appear that aluminium vessels if of suitable purity are perfectly safe for cooking purposes, and even if small quantities are conveyed to the water or food, these are without influence on the health of the individual.

the tonsils, and though, when this can be done, tonsillectomy is sometimes strikingly successful, the disease will often persist despite the fact that in the first place it was caused by tonsillar infection. Statistics do not show that the occurrence of rheumatic fever, joint pains, or chorea in children are markedly controlled by tonsillectomy, nor that susceptibility to the infective fevers is diminished by the operation. In a further class, in which symptoms such as enuresis are ascribed to reflex irritation from tonsils and adenoids, the results of operation are still more uncertain. It is only if the individual case is carefully considered, before deciding on tonsillectomy, that the results will be satisfactory. It is not to be expected, of course, that the conditions originally traceable to enlarged tonsils—such as cervical adenitis, rheumatism, or aural disease—will always clear up when the primary focus or port of entry has been removed, and fallacious conclusions are sometimes drawn from an abnormally high incidence of these conditions among persons who have undergone tonsillectomy. This abnormal incidence, where it occurs, may of course be accounted for by the fact that the conditions in question were present before operation and have not been cured. In cervical adenitis there is a further source of error in that a chronic fibrosis is apt to persist after removal of the infecting agent, and statistics which merely mention palpable enlargement of the glands are therefore open to criticism.

THE PROBLEM OF THE UNQUALIFIED ELECTROTHERAPIST.

It is now over a century since the country realised the danger of allowing unqualified and unlicensed persons to handle dangerous drugs; the Apothecaries' Act of 1815 controlled the pharmacist in a way which is undoubtedly to the public interest and which few find too severe or vexatious. Half a century later the doctors were put under a form of discipline which did, however, not extend to penalising those who practised outside the pale. Twenty years passed and the first Dentists Act provided a register and qualification for dental practitioners. Quacks may still practise medicine, for, in the words of Sir WILLIAM PRIESTLEY, accoucheur and Member of Parliament, "in England the principles of liberty are carried so far that men insist on their right to . . . being treated medically to their own hurt, if it so pleases them. The only possible limitation is to insist that the public shall be able to distinguish between those who have been educated and registered and those who have not." The abuses of unrestricted medical practice do not appear to be sufficient, in fact, to arouse public anxiety, but the position became so grave with regard to dentistry as to lead the Departmental Committee of 1920 to describe the body of unqualified dentists as "a menace alike to the public health, the registered dental profession, and the more reputable unregistered practitioners." "We are of the opinion," the Committee reported, "that in the interests of the public, dental practice by unqualified persons should be prohibited under penalty, and that nothing short of this is likely to prove effective."—a recommendation which has not been carried into law.

A precisely parallel situation has arisen to-day in respect of electrotherapy, a well-known fact including the use of X-rays, radiotherapy, ultra-violet light, and other forms of radiation. Most of these agents are

provided by Nature and have been used empirically for centuries, as Dr. E. P. CUMBERBATCH pointed out recently in his Chadwick Public Lecture. It was, he reminds us, their application by charlatans to all sorts of unsuitable maladies that brought physiotherapy as a whole into discredit at the end of last century. It was also, we believe, the activities of a small pioneer band of non-medical radiographers which in the early days of the present century did so much to bridge the gap between the engineer and inventor on the one hand, and the general practitioner on the other. There can, however, be no doubt that public interest demands some control of these potentially dangerous therapeutic agents, especially in view of the most recent experimental results of their application. The French competent authority proposes to disallow ultra-violet radiation except as part of the hospital services. Experience with dentistry suggests that the proper measure is rather a roll or register of the adequately qualified, protected by a penal clause. The Representative Body of the British Medical Association has passed a resolution affirming its belief in the necessity for a roll; the American Medical Association has already been at work on the problem for three years, and has gone a good deal further. In a recent article² Dr. A. DESJARDINS describes the work of the Council of Physical Therapy, which was instituted in 1925 by the American Medical Association to investigate and report. Its first activity was to publish a series of articles on the physiological and therapeutic action of the many different forms of physiotherapy. The Council soon found a grave lack in the medical curriculum of adequate and enlightened instruction in these methods and of suitable teachers, and it is at present co-operating with medical societies in an attempt to arrange undergraduate and post-graduate courses in physical therapy and the essential knowledge of biophysics which underlies it. The Council have also prepared a code of rules to govern the submission and acceptance of devices or methods submitted by manufacturers, and is attempting the Herculean task of reviewing the literature and preparing a scientific nomenclature. A useful report has been made on the transmitting power of various materials alleged to be permeable to ultra-violet rays. A subcommittee is gathering information on physical standards, on protection, and on other questions of fundamental concern to radiologists and is debating the vexed question of standardisation.

These activities provide some useful hints on which the medical profession in this country might proceed even if public interest cannot at present be sufficiently aroused for legislative measures. The number of physiotherapeutic quacks over here falls far short of that across the water, and we must see to it that the situation described by Dr. DESJARDINS does not arise in this country. "Instead of the natural growth resulting from gradual increase in knowledge," he says, "it soon became apparent that physical therapy had fallen into the hands of boosters who had nothing to learn from the realtors of California and Florida, and who were not troubled with petty scruples. The result was that the hapless practitioner of medicine was nearly swamped by the avalanche of incandescent, ultra-violet, and infra-red lamps, high-frequency machines, and other devices which he had to be equipped, and a host of other mysterious devices which were to revolutionise the treatment of disease and render any knowledge of chemistry and physiology obsolete. The all reports on who have to yield their relations

THE RESULTS OF TONSILLECTOMY.

TONSILLECTOMY has long been a common operation and is becoming commoner. At the Hospital for Sick Children, Great Ormond-street, it was done 2886 times in 1920 and 3909 times in 1927—an increase of 34 per cent.—and in the United States removal of tonsils or adenoids is said ¹ to account for roughly one-third of all operations among the urban population since 1924. This suggests that on the whole it is successful, and certainly the laryngologist who is careful in selection of his cases will see many gratifying successes with but few failures. Not long ago DONALD PATERSON and G. W. BRAY ² drew attention in our columns to the gain in weight shown by London children after tonsillectomy. They kept some 500 children under observation before and after operation, and found that before the tonsils were removed nearly one-fifth were losing weight, whilst the remainder were gaining little. In the six months following tonsillectomy, on the other hand, the average gain was 7 lb., which may be compared with an average gain of 2 lb. in normal children of the same age. These observers reach the conclusion that in a properly selected case there is no single operation in children's medicine that is more successful or shows such dramatic results. This opinion will be widely shared, but is by no means universal, and many of the statistical surveys recently attempted do not afford much justification for it. No doubt one of the principal causes of the discrepancy is that patients are not always well selected for the operation. The selection is far from easy, for, on the one hand, the indications for operation are very numerous and in some directions rather indefinite, and, on the other, it is often very hard to determine by examination whether any individual tonsil is unhealthy or not. It is not even a simple matter to estimate accurately the size of a tonsil, for some of them are deeply placed and embedded, whilst others are prominent and superficial. Nor are we sure that an enlarged tonsil is necessarily unhealthy, for sometimes enlargement may be due, as J. H. P. PATON ³ states, to an increase in the number and activity of the germinal follicles—a physiological response, apparently, to some stimulus whose nature is unknown. Sometimes tonsils cause symptoms mechanically by their mere enlargement, and this may make removal advisable; but it is in this group that most of the unnecessary operations fall, especially since routine inspection of large numbers of school-children was started. In doubtful cases examination of the throat with a tongue-depressor is not enough to decide the question of tonsillar sepsis. Redness of the surrounding pillars is a valuable guide, but may arise from other sources, such as septic teeth. Further help may be got by squeezing the tonsil. If definite pus be thus obtained infection of the particular crypt is proved, but a little thin secretion is not conclusive evidence of infection, nor are one or two hard, chalky, or caseous masses in the crypts a proof that toxins are being absorbed from them. It is hard to get reliable bacteriological evidence in these cases, for there are many organisms in the mouth, and a swab taken from the surface of the tonsil will necessarily collect them; it is even difficult to prove that the organisms found in material squeezed from the crypts are pathogenic. Even after removal of the tonsil it is impossible, as R. B. LUMSDEN ⁴ remarks, to isolate organisms from its

substance uncontaminated with those from the interior of the crypts; but the differentiation here is perhaps of little importance, for toxins can doubtless be absorbed from the tonsillar crypts. In the more difficult cases of this class the history is of great importance, and must often be the determining factor in deciding for or against operation. A history of attacks of sore-throat, especially if associated with increased symptoms of toxic absorption, strongly suggests that the tonsils are at fault.

Another cause of the comparatively bad results of tonsillectomy, as shown in group statistics, is that often the tonsils have not been completely removed. The results of treatment cannot fairly be judged from cases in which it has not been properly carried out, and statistics certainly indicate that greater care and skill should be exercised in the performance of an operation which is not so easy as is generally believed. In America J. P. CLARK ⁵ found tonsil tissue remaining in 41 per cent. of 143 patients who had been operated on three or four years before, while P. S. RHOADS and G. F. DICK ⁶ found "fairly large" pieces of tonsillar tissue in 73 per cent. of student nurses whose tonsils had been removed. In Scotland, in a large school for the daughters of the well-to-do, PATON found a visible tonsil on one or both sides after previous operation in 54 per cent. of 182 girls. From a statistical consideration of the occurrence of enlarged cervical glands he concludes that the lymphoid tissue regenerated after operation is not infective, but he does not perhaps take into sufficient consideration the possibility that this glandular enlargement is often merely the quiescent result of past infection. On the other hand, RHOADS and DICK find from bacteriological examination that the "stumps" of tonsils removed by a second operation are much more heavily infected than tonsils removed for the first time, and they quote a series of cases which improved strikingly after the removal of tonsillar tissue left by a first operation. All authorities now seem agreed that the tonsils should be removed completely or not at all, but the technique of the operation remains a matter of personal preference and skill. PATERSON and BRAY say that a complete dissection of the tonsil and lingual tonsil must be made, as is the custom at Great Ormond-street, but other authorities show good reason for maintaining that the faucial tonsils can be completely removed with the guillotine by the method of WHILLIS or of SLUDER, and that this is a less severe and equally successful method in suitable cases. Whatever is done, a considerable amount of skill is essential.

The operation is nowadays performed in the treatment of a great variety of conditions. In simple enlargement without symptoms we believe it is seldom necessary and is perhaps done too often. When enlargement of the tonsils and adenoids is associated with disturbance of function of other organs, especially with interference to respiration or to the Eustachian tubes, either mechanically or by spread of inflammation, intervention of some kind is obviously called for, and it is in this class of case that the largest proportion of successes is obtained. There is another group in which tonsillar sepsis produces distant effects on the alimentary tract, the appendix, or the gall-bladder; by absorption of toxins into the blood stream it may cause general debility or the group of symptoms generally called rheumatic. In this group it is harder to prove the culpability of

anaphylactic interpretation. It was also noticed that first bites might remain quiescent and invisible for 10 days and then flare out into violent wheals when a second biting was imposed on another part of the body — a pretty illustration of an intense local sensitisation due presumably to the local accumulation of antibody.

NURSING HOMES IN LONDON.

THE impressions left on a patient by a sojourn in a nursing home are so often coloured by fear or softened by gratitude that they are largely discounted by the doctor who habitually uses the home and finds it satisfactory in essentials. It is only when he himself or a member of his family is condemned to a term of confinement within its walls that he becomes interested in administrative details, and sympathetic both with the difficulties of the owner of the home and with the bewilderment of the patients and his friends in the face of a routine which seems unreasonable if not sometimes positively unkind. A doctor has recently confided to us his experiences at a small nursing home of high repute. The food was well and daintily served, but the cooking was indifferent and the menus often ill-chosen. He had made no arrangement for a "special" since he had been assured that the (reduced) charge of 12 guineas would cover the necessary nursing; as a result, in the nauseating day which followed his operation he had been left for long periods with a basin at his side and a bell at his elbow. The bell was answered promptly except at night when, if the only nurse on duty was attending to another patient, there was no mechanism whereby she was informed that her services were required. His discomfort was increased that day by sensations of bruising and stiffness, accounted for by the fact that when still anaesthetised he had been carried round the corners of narrow flights of stairs doubled up in a canvas sheet. The kindness and attention he received from individual nurses, some of whom were not fully trained, deserved high praise. It is the unsuitability of the premises for their purpose to which he attributes most of the avoidable inconvenience, and also the convention whereby the inclusive fee does not ensure full-time nursing service for each patient while he is acutely ill. The ordinary patient enters a nursing home in a state of acute physical and mental distress, and is often completely reassured by the friendly confidence of the sister or matron who greets him and his friends. In the very best of homes—not necessarily the most expensive—his confidence is never allowed to flag, the whole atmosphere being designed to foster and maintain it. But too often a period of disappointment ensues, especially where the fees charged are high in comparison with the patient's income and ordinary expenditure, and he spends restless days worrying over the contrast between the charges made and the attention provided, often comparing the nursing home to a good hotel to its great disadvantage. Since the housing shortage and the popularity of flats there has been a great increase in the number of patients of the middle class who have to go to a nursing home when they are ill, and there is a growing impression that the provision made for their welfare might be considerably improved.

THE current number of the *University College Hospital Magazine* (1928, xliii, 200) contains an account of some interesting experiments made by Prof. A. E. Boycott which go to show that the ordinary irritable wheal which often follows the bites of midges, mosquitoes, and other insects is an anaphylactic or allergic phenomenon. Persons show no reaction the first time they are bitten by any species of insect, but subsequent bitings may sensitize them and they then respond in the familiar way. They are presumably sensitized to the protein which the insect injects with its saliva. Decisive experiments are obviously hard to make with our native midges, &c., since no one knows exactly what has bitten him in the past. The present experiments were made with the small sandfly *Phlebotomus papillipes*, bred at the London School of Hygiene and Tropical Medicine by Dr. P. A. Buxton, from larvae sent from Jerusalem by Dr. Oskar Theodor. This insect occurs all round the Mediterranean but does not come near England than the neighbourhood of Paris; it may, therefore, be presumed that people who have stayed at home in this country have never been bitten by it. Used throughout the same batch of flies, Prof. Boycott found that four such people gave no reaction at all to their first bitings; in another individual who had been freely exposed to *Phlebotomus* in the East ten years ago, the first application of the insect was followed by immediate wheals. Of the four natives, one was doubtfully positive as being bitten for the second time two days after the first biting, and gave a violent reaction to the third biting, which was repeated seven days after the first; one gave a large reaction to the second biting on the third day, and gave a violent reaction to the third biting, which was repeated seven days after the first; one was negative on the third and seventh days, but strongly positive on the thirteenth and twentieth days. All four therefore became sensitive and developed a positive reaction to *Phlebotomus* as a result of the very small and distant bite as a first step. The third of the experiments was likely to be successful but not safe, after the first biting the third and seventh days were absent, but the positive reaction on the thirteenth and twentieth days was quite as marked as in the other

The keeping of a nursing home is a business like any other; the profits must depend on keeping down the overhead charges to the lowest point compatible with efficiency. This fact has been recognized by Parliament and the Nursing Home Registration Act of 1927, which came into force last July, is obviously designed to prevent the neglect of patients and to ensure that a minimum standard of comfort and attention is provided. As a result of this Act the London County Council has issued a list of nursing homes, and is endeavoring to ensure that all nursing homes will be supplied with the minimum standard of comfort and attention which the Council has decided upon. The standards are based on the latest existing practice and are to be revised from time to time.

cyanosis; adrenalin, atropine, and calcium preparations for the spasmodic condition of the bronchioles; and cardiac stimulants such as digitalis and camphor for the cardiac failure (as shown by the enlargement of the liver) are all advisable. Sedatives should be given to calm the child and promote sleep after the attack has been controlled, and in the case quoted these measures quickly restored the child to normal, so that 40 hours after this acute and severe respiratory affection the child was sitting up in bed with only a few adventitious sounds in the lungs to indicate any past disorder.

PREMEDICATION WITH ANÆSTHESIA.

THE discussion at the Anæsthetic Section of the Royal Society of Medicine, following Mr. E. S. Rowbotham's paper on the use of paraldehyde, makes it plain that there is still a good deal of difference of opinion with regard to the advantages of using sedative drugs before the administration of anæsthetics proper. It certainly would appear a priori that multiplication of injected drugs as in Gwathmey's so-called "synergistic" method is undesirable. To begin with, there is little or no definitely ascertained knowledge of the action of these drugs in combination. The very existence of "synergism" has been denied on the grounds of experimental and pharmacological evidence against it, brought forward most cogently by a countryman of Gwathmey's. Obviously the repeated hypodermic and rectal injections are a nuisance unless they procure some very decided advantage. They entail a large amount of trouble for nurse or anæsthetist and a certain amount of inconvenience for the patient. Nevertheless there are many patients for whom it is a great advantage, if not an actual necessity, that the taking of the anæsthetic should be preceded by a powerful sedative of some kind. If that sedative effect can be procured by a single hypodermic or a single rectal injection it appears to us that this is much to be preferred to several injections. One speaker at the meeting to which we have referred above recommended morphine and scopolamine for this purpose, and another urged strongly the use of avertin, which is given rectally, as paraldehyde is. It appears that paraldehyde alone is insufficient generally to procure the desired drowsiness. Avertin is perfectly efficient in this respect. The long sleep that follows the use of efficient premedication is regarded by some of the speakers as a desirable by others as a dangerous consequence. All were agreed on the amount of extra care and trouble that devolves on the nursing staff in institutions where effective premedication is widely employed. There was also a good deal of comment on idiosyncrasy towards some of the drugs used, especially hyoscine, and it was recommended that when possible preliminary trial of a patient's reaction to this drug should be made by the use of minute doses.

THE APPLE.

THE apple as physician has been so abundantly introduced to everyone that medical men cannot but feel an interest in the apple as patient, and the Report for 1927 of the Food Investigation Board might well prove a Christmas best-seller amongst the medical profession, for it devotes many pages to the physiology and pathology of this fruit. An apple consists of sugar, acid, cell-wall material, soluble pectin, minerals, and an organic substance, allied to the carbohydrates, of which the chemical nature is still unknown. The traces of alcohol increase as the fruit rots. Fungus invasion is one of the most serious apple diseases, and its investigation follows lines very familiar to the bacteriologist. It has been found that every individual apple has its characteristic resistance, and that the rate of invasion rises or falls according to the breed of apple and the experimental conditions. The differences in resistance can be correlated with differences in chemical composition of the fruit. Low water content, high acidity, high

potash content, and low nitrogen content are associated with high resistance, and the converse is also true. We cannot yet reduce the complicated resistances of the human body to simple chemical terms, but it seems likely that even this will come in time. Another disease of apples is "low temperature internal breakdown"—the hypothyroidism of the vegetable world. This also depends to some extent on the constitution and metabolism of the fruit, but environmental factors play their part. The onset is accelerated by reducing the concentration of oxygen or increasing the amount of carbon dioxide in the storage room. On the other hand, if the storage temperature is kept above the critical range of susceptibility, the reduction of oxygen and increase of carbon dioxide lengthens the life of the apple. Gas storage at about 40° F. is therefore better than cold storage. Long life is related to small size and low respiratory activity and delayed climacteric. The largest apples have the highest respiratory activity and the shortest life—though this is not quite without exceptions, as one tree tested bore large rosy apples which took an exceptionally long time to reach the climacteric peak of respiratory activity. Keeping quality also improves with the heaviness of the soil, and there is a general correlation between the keeping quality and the "available" potash and phosphoric acid in the earth from which the trees spring. A low nitrogen, low acid, and high sucrose content means a good keeper, and apples vary considerably in their composition. It is hoped that this variation may be controllable, as it has been shown to depend to some extent on cultural factors. Apples grown in the warmer parts of England are better keepers, for they have low acid values and high amounts of sucrose. The amount of nitrogen does not seem to depend much on the environment, and research is in hand to find out what internal factors govern it. It is clear that these investigations are of immediate practical value to the fruit-grower and, through him, to the consumer. It is conceivable that they may one day point the way to research on the metabolism of more highly organised forms of life.

PARKINSONISM AND THE ATROPINE GROUP.

SOME months ago a good deal was heard of the value of stramonium in the treatment of chronic encephalitis, and it is interesting to have a report from St. Bartholomew's Hospital on the merits of the drug. Dr. E. A. Carmichael and Dr. F. H. K. Green, of the Medical Professorial Unit, in their clinical and instrumental study of the effects of stramonium, hyoscine, and other alkaloids, find that stramonium was more efficacious than the others in alleviating the symptoms of the bradyphrenic parkinsonian. While they were disappointed with the pills of powdered stramonium leaves recommended by certain French writers, they got uniformly good results with tincture of stramonium. In considering this favourable opinion, it must, however, be borne in mind that it does not agree with the experience of certain other investigators. Thus in a paper on Oculogyric Crises in Chronic Epidemic Encephalitis, published in the current issue of *Brain* (1928, li., 285), Dr. P. K. McCowan and Dr. L. C. Cook discuss the palliative treatment of parkinsonism, and state that after prolonged systematic trials of the atropine group of drugs they find belladonna and stramonium inferior to genoscopolamine and hyoscine by the mouth. They point out that with few exceptions greater benefit accrues from the use of hyoscine hydrobromide by the subcutaneous route, but rightly emphasise the fact that injection should not be resorted to, however, in any individual case unless its greater benefits have first been demonstrated. It is evident that in the atropine group we have a number of drugs definitely useful in the treatment of parkinsonism and its concomitant mental symptoms, but (as so often in medicine) the patient as well as his disease must be considered. Only by trial in

XV.

THE DETERMINATION OF THE PRESENCE AND SIGNIFICANCE OF REDUCING SUBSTANCES IN URINE.

By E. C. DODDS, M.D., PH.D., M.R.C.P. LOND.,

PROFESSOR OF BIOCHEMISTRY, UNIVERSITY OF LONDON;
DIRECTOR OF THE COURTAULD INSTITUTE, MIDDLESEX HOSPITAL.

II. THE BIOCHEMIST'S RESULTS.

AFTER having ascertained that the patient's urine reduces Benedict's solution, the practitioner is faced with a somewhat difficult problem. He has to determine whether the condition is one of diabetes mellitus on the one hand, or whether it is some harmless form of glycosuria on the other. In the majority of cases he will be helped by the manner in which the patient happened to come under his control. If the patient has lost a great deal of weight and is suffering from the classical symptoms of diabetes mellitus, the duties of the physician will be obvious. By far the most difficult type of case is that in which the urinary reducing substance is discovered more or less by accident during a routine examination, such as for life insurance. The problem here is that of an apparently normal person with no symptoms whatsoever, whose urine is found to reduce Benedict's solution. In this case a fermentation test should be performed according to the method described last week. If a positive result is obtained, there can be no doubt that the reducing substance is glucose. If, however, no fermentation occurs in the urine, then it is far better for the practitioner to send the specimen to a laboratory for further analysis, since it will only be in exceptional circumstances that he will have at hand the necessary materials and apparatus for determining the nature of a reducing substance which is definitely proven not to be glucose.

Let us assume, however, that the urine was fermented by yeast and, therefore, that glucose is present. The possibilities are:—

- (1) The patient may be suffering from the early stages of diabetes mellitus and will in time develop all the usual symptoms.
- (2) He may have a minor degree of carbohydrate intolerance which is shown by the appearance of glucose in the urine after a meal.
- (3) He may be suffering from renal glycosuria.

Tests for Acetone Bodies.

In the first place, the practitioner should test the urine for acetone bodies—that is to say, Gerhardt's and Rothera's tests should be performed.

Gerhardt's test is done by adding 10 per cent. ferric chloride to the urine very slowly. If the concentration of acetoacetic acid in the urine be 0.007 per cent. or more, the solution will turn a deep red, persistent colour. This reaction is only given, however, when large quantities of acetoacetic acid are present and is, therefore, a test that the patient is in a very bad condition. About a report is drawn to one or two fallacious conclusions. The first is that, if the patient has not improved or any other physical data, then the urine will show a positive reaction to the addition of ferric chloride. This is a fallacy, for the reaction obtained with

distinguished from the true, since the colour is much darker and of a more violet shade, but if any doubt is felt, then it is a good plan to boil some of the urine. On the addition of ferric chloride there will be a negative reaction if the colour was due to acetoacetic acid, but if it was due to the presence of drugs, then the reaction will still be positive.

A more satisfactory test for acetone bodies than the above is Rothera's test. This is performed by taking half a test-tube of urine and shaking it with about three-quarters the amount of ammonium sulphate crystals until the urine is saturated. A few drops of dilute sodium nitroprusside are added, followed by two or three drops of 10 per cent. ammonia solution, and the whole is well shaken. A positive reaction consists of the development of a deep permanganate colour, varying in intensity with the amount of acetoacetic acid present.

If these tests are both positive then it is fairly safe to conclude that the patient is suffering from diabetes mellitus, since acetonuria is very rarely present to any marked extent in conjunction with sugar in the urine except in cases of diabetes mellitus.

Glucose Tolerance Tests.

On the other hand, it may be that the Gerhardt and Rothera tests are negative, thus indicating that the condition is either renal glycosuria or possibly one of slight carbohydrate intolerance, as pointed out above. There is, unfortunately, only one sound and reliable method of distinguishing between these types of glycosuria, and that is the performance of a glucose tolerance test upon the patient. This procedure, however, is not very suitable for the practitioner, and the patient should always be sent to a laboratory or institution for the test to be made. The patient is taken in the morning before he has had breakfast and a specimen of blood is collected. Fifty grammes of glucose dissolved in water are administered to the patient and further specimens of blood are taken at half-hourly intervals after the meal for two hours. Each of the five specimens of blood is analysed and the sugar content estimated. The original height, together with the rise and fall of the blood-sugar during the period of the test, is a clear indication of the condition of the patient. The characteristic sign of renal glycosuria is a subnormal sugar content throughout the experiment, while the severe diabetic shows a very high figure which continues to rise during the whole of the two hours. This test is extremely useful for judging the severity of the condition and also for detecting the very early stages in the production of diabetes mellitus. In such a case the patient shows a "lag" curve—that is to say, there is a sugar-storage lag indicated by a very sharp rise in the blood-sugar above the normal limit, but in this type of curve the sugar content falls to normal again within the two hours.

However, if the report from the laboratory or the result of the practitioner's own tests indicate that lactose is present in the urine, it is not necessary to take any account of this. Lactosuria is a condition occurring almost solely in pregnancy and lactation and need cause no anxiety. Often one is misled by finding a reducing substance in the urine together with the presence of acetone bodies in a pregnant woman, and in many cases this condition has been treated by strict diabetic measures. Actually the condition is a normal one, since acetone bodies are usually found in the urine during pregnancy, and the reducing substance is lactose. A word of warning must, of course, be given as to the possibility of true diabetic mellitus supervening during pregnancy; the nature of the reducing substance must always be determined.

Should the report from the laboratory indicate the presence of glucose, again the practitioner need take no further steps other than to assure the patient that the condition is harmless. Renal glycosuria is one of the polymorphous manifestations of renal malfunctioning by which an individual is able to excrete far more glucose than is deleted as effect upon the patient's health.

trained and untrained nursing staff required will depend on the types of patient received. According to the memorandum, in the ordinary mixed home there should be, as a general rule, two day nurses and one night nurse for each six patients. At least one nurse must be on night duty whenever there are four or more patients at the home or when any patient is acutely ill. Wherever practicable suitable sitting-room accommodation should be provided for the nurses. Particulars of the standard minimum equipment suggested by the Council are appended, and the list of requirements does not seem to us at all excessive. For example, for each bed the linen provided should be three pairs of sheets, three draw-sheets, six pillow-cases, four bath towels, four face towels; also two sets of blankets, each set consisting of two upper blankets and one under blanket. The provision of stretchers or carrying-chairs is considered desirable; also of proper sluices for the cleansing of bedpans where possible. The Council considers the keeping in nursing homes of domestic animals, such as dogs and cats, to be undesirable.

Undue restriction of visiting hours, inaccessibility of the sister in charge, the routine use of certain favourite purgatives irrespective of the habits of the patient, disinclination to allow the patient to get up until a day or two before he is discharged—all these defects are common enough, and are an indication of inconvenient structure or insufficient staffing, coupled with lack of imagination on the part of the authorities. It is the doctor's business to ascertain whether the patient's convalescence is being retarded by feelings of resentment against the discipline under which he is placed; very often a word explaining the difficulties of administration will serve to put an entirely different complexion on the matter. Perhaps the most important way in which the practitioner can help is to arrange that at each visit he sees the patient, if only for a few minutes, in the absence of either the nurse, sister, or matron. Often, if ample opportunity is given for complaints, none will be made, but the patient will feel that his comfort and welfare are still in the hands of his own trusted doctor, who is guarding his interests, physical and financial, with unremitting attention.

THE MEDICAL DIRECTORY.

THE Medical Directory for 1929 reaches us on Dec. 10th, 1928. It contains evidence of careful revision, the indexing has been improved, certain alterations have been made in headings for the sake of clearness, but the sum-total of change amounts to very little, for, in its eighty-fifth year of issue the publishers of the Directory have little to learn in the way of arrangement or convenience. The only doubt we have is in regard to the binding, which may be good enough for average use, but unfortunately does not survive 12 months of constant office reference. Following the title-page is the usual numerical summary of the medical profession, which shows an increase of 857 entries in 1929 over those of 1928. As usual, the change is distributed unequally over the seven sections, for whereas London (+174), the provinces (+377), Wales (+9) and Abroad (+371) show increase more or less substantial, Scotland (-46), Ireland (-13), and the Services (-15) each show a small decrease. On this page appears a new table giving the numerical progress every decade from 1850 to 1920, in which it is instructive to note that the total number of names in the Directory doubled between 1850 and 1870 and again between 1870 and 1910. The introductory pages preceding the name index have been augmented from 116 to 122, the increase being due almost entirely to the inclusion of a directory of members of the Chartered Society of Massage and Medical Gymnastics. The space devoted to the Incorporation of Certified Masseurs and Masseuses has been proportionately reduced. Of strictly medical information the only addition is the enumeration of the Parliamentary Medical Committee, which, as everyone knows, includes the names of all

the Members of Parliament who possess a medical qualification, but, as everyone does not know, also includes the names of four co-opted University representatives—namely, Colonel John Buchan, Sir Martin Conway, Sir Alfred Hopkinson, and Mr. J. J. Withers. The hon. secretary of the Committee is Dr. Drummond Shiels. In the local list for Ireland care has been taken to define the limits of the Free State and Northern Ireland. Finally, the section on the Health Resorts of Great Britain, Ireland, and New Zealand shows signs of careful revision and includes an interesting graph of the temperature of the sea in summer at various marine resorts. The Medical Directory is published by Messrs. J. and A. Churchill at the price of 36s.

AN OFFICE EDITION OF THE MEDICAL AND DENTAL REGISTERS.

IN order to facilitate the work of those who find it essential to know whether a medical practitioner is legally qualified or not—such, for instance, as officials of insurance committees, chemists, and druggists—the General Medical Council publish an office edition of the lists contained in the Medical Register, giving the names and addresses of all registered practitioners. This office edition is bound in paper boards, and issued from the office of the Council, 44, Hallam-street, London, W. 1, at the special rate of 7s. 6d. post free. Similarly the Dental Board publish an office edition of the Dentists Register containing the names and addresses of all registered practitioners and the local list at the price of 4s. post free. We are asked to state that in both cases copies are only issued at this price if they are ordered and paid for prior to Dec. 31st of the year preceding that of publication.

THE ARMY MEDICAL SERVICES.

THE reconstitution of the Army Medical Advisory Board, which is to include four civilian members of the medical profession, is noted on p. 1262, where the new personnel is set out. The Board will be at the disposal of the Secretary of State for War, if he desires to consult them on any question of policy in connexion with the Army Medical Services. Normally the Board will meet three times a year, but the civilian members may arrange additional meetings on giving the necessary notice. It has also been decided to appoint a committee, to be known as the Army Medical Directorate Consultative Committee, which will contain six civilian members of the medical profession who hold instructional or other appointments at university centres or medical schools. This committee will be charged with the duty of advising the Director-General Army Medical Services on the supply of candidates for the R.A.M.C., on post-graduate and other courses, and other administrative or purely professional questions. The civilian members of the Board and of the Committee are admirably representative of medicine, surgery, and physiology; doubtless, machinery exists whereby a pathologist may be co-opted on the last-named body.

Dr. Leonard Gregory Parsons, F.R.C.P., has been elected to the new chair of Infant Hygiene and Diseases of Children in the University of Birmingham.

THE Belfast Public Health Committee has recommended Dr. Charles Samson Thomson, medical officer of health for Deptford, for the post of medical superintendent and officer of health for Belfast.

FOLLOWING the award of the Nobel Prize for Medicine for 1928 to Prof. Charles Nicolle, director of the Pasteur Institute of Tunis, it is announced that the Nobel Prize for Chemistry is to be conferred on Prof. Adolf Windaus, of the Institute of General Chemistry at Göttingen, who has taken a large share in research on the photochemical formation of vitamin D.

Special Articles.

GENERAL MEDICAL COUNCIL.

WINTER SESSION, 1928.

EXECUTIVE COMMITTEE.

THE meeting of the Executive Committee which preceded the full winter session of the General Medical Council was exceptionally full of interest to the medical profession at large, and we make no apology for giving a rather lengthy summary of a number of topics then discussed.

International Reciprocity.

The Committee considered the draft of a proposed International Convention on the Treatment of Foreigners, sent to the Council by the Privy Council for their observations. The relevant clause prescribes that nationals of one signatory who are allowed to live in the territory of another shall be treated equally, in law and in fact, with those of the country in which they live, and allowed to carry on all occupations permitted by law to its own nationals. If especial titles or guarantees are required, as in the practice of medicine, nationals of another signatory shall be allowed to exercise their occupation on submitting titles identical with those required of nationals or recognised as equivalent by the signatory concerned. The protocol includes a declaration that it is desirable that arrangements for the recognition of the equivalence of such titles or guarantees should be concluded between countries in which the necessary guarantees of equivalence appear to exist. The Committee resolved that the Privy Council should be informed that the Council regard it as desirable that agreements of this kind should be made, and that, "so far as Great Britain is concerned, these principles have always been acted upon so far as possible."

The absence of such reciprocity has led in the past and may lead again to international reciprocity. An example of unfortunate misunderstanding was provided by another communication from the Privy Council. This concerned a medical missionary with an Edinburgh degree who, finding himself temporarily in Haiphong owing to the trouble in Southern China, had asked the French authorities for permission to practise. The Governor-General had refused, saying that he believed persons were not allowed to practise in England by virtue of French diplomas. Although the Council had replied that the restriction only applied to registration and not to practice, and had suggested that the Governor, considering the exceptional circumstances, might allow this doctor to practise to the same extent that was permitted to French medical men in this country, their request was not granted.

Universities of Bombay, Lucknow, and Madras.

At its meeting the day before the summer session the Committee had decided to continue to recognise the M.B., B.S. of Bombay University provided the Council received, before July 1st, 1929, a satisfactory report from the Indian Government Inspector on the first Final Examination to take place under the new regulations in the academic year 1928-29. In the revised regulations sanctioned by the Government in October, 1928, there is no provision for a Final Examination before April, 1931. The Committee passed a resolution of regret. It would appear that by last summer's resolution the Bombay qualification will cease to be recognised from the summer of next year until the receipt of a favourable report in 1931.

The Committee considered a report by Colonel A. H. Proctor, who had been appointed by the Indian Government to inspect the examinations in Lucknow University on behalf of the Council. Colonel Proctor, who is the Presidency Surgeon in Madras, concluded

that the final examination was of a satisfactory University standard, and recommended that the recognition of the M.B., B.S. be continued subject to the production and assessment of the obstetrics and midwifery reports at the examination, and to one other alteration of detail. The practical work in obstetrics is, he says, hindered by the purdah system, but this deficiency should be made up by the building of the new maternity hospital. The medico-legal examination is given great prominence—though Colonel Proctor reported that the questions did not sufficiently test the candidate's knowledge of mental diseases—and the examination in ophthalmic surgery is obligatory, and regarded as extremely important. He spoke very highly of the practical examination in pathology. The students' command of English was sufficiently good for conversation and to appreciate clinical teaching, but did not allow them to do their knowledge full justice in the written papers. Sir Norman Walker's note appended to the report commended Colonel Proctor's careful study of the position.

The University of Madras had reported on the changes and improvements carried out since the recent visit of Sir Norman Walker, and the Committee observed with satisfaction that most of the points which he had criticised had been attended to.

Rangoon University.

Colonel R. A. Needham, inspecting Rangoon University examinations in 1927, had reported unfavourably on the new regulation exempting from the premedical course in chemistry, physics, and biology those students who had passed the intermediate examination in them. The Committee considered a long reply by the University authorities, who maintained that to force these students to study the same subjects for another year would be a waste of time and would extend their course to the prohibitive length of eight years; the University invited inspection of its final examination, the standard of which was second to none in the East. The Committee, while maintaining their own views in regard to the points of difference, suggested the appointment of Colonel Needham to inspect the final examination in March.

Initials in the Register.

In 1924 a registered medical practitioner had applied to have the initial H. substituted in the Register for his middle name. This had been done with an addendum setting out in full the name as it previously stood. The practitioner requested that this addendum be omitted. The Committee directed that he be informed that if he complied with the prescribed requirements the initial H. could be omitted and all reference to his second name would disappear in due course. It has never been customary to enter initials in the Register in place of full names. It has only been done once, when Mr. Charles C. Elliott in 1922 produced evidence that this was his full name, and entered as such on his birth certificate and diplomas.

Education of Medical Students in Obstetrics.

A memorandum by the President of the Council on this subject formed an appendix to the report of the Committee; it set forth the development of the Council's efforts to attain a satisfactory solution, and their present recommendations. Mr. H. L. Eason summed up the position as follows in his memorandum on the training of medical practitioners and midwives in England:—

In the public interest there should be an ample supply both of medical practitioners and of practising midwives, and the training in obstetrics of both classes should be of the highest possible standard. If in the provision of clinical material for their education their respective interests clash, the solution should be sought in an extension of the field from which this provision can be obtained. And the problem will be simplified by restricting as far as possible the requirements of a certificate of training as a midwife to those who intend to practise as midwives.

the age and intelligence of the group. The records used in the test are made from a series of numbers transmitted by a voice that varies from a loud conversational tone to a barely audible whisper. In the last two years this device has been used increasingly in testing the hearing of children in the public schools. We have now a report¹ by Dr. Frank A. Laurer of the results of a survey of 4419 children in the schools of Syracuse, New York, where the Milbank Foundation is conducting its successful health demonstration. The total number of children found to have impaired hearing was 502, but of these 421 were in the class of "borderline" impairment. Fifty-six suffered a moderate loss of hearing and 25 a severe loss. Two hundred of these students escaped the special examination by an aurist, but the recommendations made in the case of the remaining 302 show clearly to what conditions the defects were due:—

Tonsillectomy ..	187	Medical attention for	
Removal of wax ..	54	otorrhoea ..	33
Inflation ..	13	Further observation ..	15

It thus appears from this survey that rather more than 10 per cent. of the school-children had sub-normal hearing and that about 80 per cent. of these were suffering from defects that were remediable. Such a result seems to justify the routine use of the audiometer.

Deaths from Heart Disease.

An interesting analysis of mortality from diseases of the heart is published in the Vital Statistics Bulletin of the Pennsylvania Department of Health. This State has the largest vital statistics experience of any State health department, since New York City is not included in the figures for New York State, whereas Philadelphia is included in the statistics of Pennsylvania. Here as elsewhere there has been a rising rate from heart diseases from 133.5 per 100,000 in 1906 to 210.6 per 100,000 in 1927. The upward trend has been marked over the whole period of 22 years. In this time the rates for endocarditis and myocarditis and for angina pectoris have doubled. "Other diseases of the heart" also show a marked increase, the only decrease being in pericarditis—from 1.4 to 1.0 per 100,000. Some of the upward trend is explained by the increasing number of older people in the State, but even the standardised rate has increased from 142 to 203. However, when the age specific death-rates are calculated it is found that in the age-groups under 30 the death-rate from heart disease has definitely decreased. The median age of death from this cause is now 66 years, or three years older than in 1906, and the most marked increase of rate is in the age-group 80 years and over. It thus appears that the increasing rate is more an evidence of survival to the age of senility than of any increase in the specific causes of heart disease.

The Eyesight of School-children.

At the recent conference in New York of the American National Society for the Prevention of Blindness the responsibility for conserving the sight of the child was placed upon the teacher. Dr. Harry B. Burns, who directs the department of hygiene in the Pittsburgh public schools, reported from 18 years' experience that parents cannot deal adequately with sight-conservation. The school, he thinks, is the logical organisation to assume responsibility for the children's sight. While the ultimate technical service is that of the oculist, assisted by school physician and nurse, the immediate responsibility for vision testing must of necessity devolve upon the class-room teacher. Dr. William H. Holmes (superintendent of instruction, Mount Vernon, N.Y.) urged the consideration of proper lighting facilities in the home; architects, he said, fail to provide the means for correct illumination. Children even in play should be placed where their eyesight can develop normally under proper illumination. Dr. David E. Gillette (Department of School Health, Syracuse) condemned polished

desks, and suggested that publishers should avoid glazed paper for school books.

Medico-political Questions.

The committee on civic policy has reported to the Medical Society of New York County that the practice of fee-splitting is one of the most vexatious and persistent evils with which the society is called upon to deal. While in some instances a manifestation of economic stress, in others it is the product of commercialism and greed. A questionnaire on the subject was handed to members along with their voting-papers for new officers, to be deposited unsigned in a separate ballot-box. Information was asked for as to income, as to whether or not the practitioner believed his income to be adversely affected by "dispensaries, pay-clinics, life extension institutes, and health clinics, as at present conducted," as to fee-splitting, as to whether the family doctor receives adequate pay, and as to whether he should be associated in the treatment of a case sent to a hospital by a consultant. The questionnaire gives a clue to the burning medico-political problems of the moment.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1927 statistics of nine administrative counties:—

Name of town and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Infant and 1-6 yrs. mortality.	Diphtheria, &c., under 2 years. Mortal mortality from childbirth.

Somerset.

Dr. W. G. Savage expresses satisfaction with the spurt in housing activities during the last few years. Thus the houses built in the urban districts during the last three years have been 581, 974, and 1393, compared with an average of 400 for the previous four years; while the figures for the rural districts are 812, 1217, and 1442, compared with an average of 502 for the previous four years. There has been a need for houses all over the country, but some of the authorities have been active while others have not. Many of the new houses are in towns, but many are in villages and parishes, where no or few houses have been built for generations. As a rule the sites have been well chosen, the spacing adequate with good gardens, and the architectural features harmonious. Dr. Savage gives particulars of the houses built in all the districts under the five schemes of Government

¹ See Amer. Jour. of Public Health, November, 1928.

physician to the American Hospital, said the charge was reasonable. In answer to the judge he said he had actually received 200 guineas for going to a patient at Newcastle. After consulting a railway guide, the judge observed that Newcastle was 266 miles from London, to which Dr. Humphreys replied that he must have misread the figures in making his charge. The judge disallowed the item of 30 guineas and substituted the figure of 26; he said that a doctor should make it clear if he is going to charge a special fee of this nature. The upshot of this decision is first that the sum claimed might have been regarded as reasonable if warning had been given; and, secondly, that the court seems to regard it as unreasonable for a specialist to charge a fee of more than four guineas for a special visit to a patient at Eastbourne—a conclusion on which the medical profession will form its own judgment. In so far as the mileage basis is put forward as a matter of custom, it must be remembered that a custom to be legally valid must comply with certain conditions. It must not only not be contrary to the public interest; it must also be definite, well known, and universal. If patients can say that they never heard of such a custom, then it can hardly be called well known; if it is pointed out that a claim is for 30 guineas and that the distance from London to Eastbourne is not exactly 30 miles, the discrepancy is an obstacle to definiteness. It would, therefore, appear better not to insist too much on the basis of custom but to rely on that of reasonableness.

As a matter of fact, as a writer has recently pointed out, the mileage basis is of respectable antiquity. In the eighth volume of "Farington's Diary" there is mention (under the entry for Oct. 25th, 1818) of a Dr. Ainslie's visit from London to a patient at Hastings. "He had 66 guineas, his fee being reckoned at a guinea a mile." It is a pity that this excellent precedent was not quoted to Mr. Justice McCardie who would have appreciated it. Travel, of course, was a different matter a century ago, but then 66 guineas purchased a great deal more than it does to-day. "Farington's Diary," by the by, contains much curious information about medical fees. He quotes a Dr. Baillie as "reckoning to get £10,000 per annum"; Astley Cooper, he believes, makes £22,000 a year, and got a fee of £1000 for operating for stone on "an elderly gentleman from Jamaica."

"Taxing" Doctors' Bills.

The uncertainty of medical fees undoubtedly leads to occasional surprises on the part of the patients where frequent periodical accounts are not rendered. Dwelling upon such occasions, "A Solicitor," writing in the *Birmingham Gazette* of Nov. 28th, makes the ingenious suggestion that doctors' bills should be taxed like those of a solicitor. A lawyer's bill, he explains, goes before an official called a Taxing Master, who disallows such items as he considers unnecessary, improper, or excessive. There is, as he points out, a fixed maximum scale for charges in many matters undertaken by solicitors, and he thinks doctors might be similarly regulated.

The legal and medical professions, in the essentially personal relationship between their members and their clients or patients, have much in common. Doctors will welcome any suggestion from solicitors for the appropriate reward of the services they render. The solicitors are in the enviable position of having had most of their fees substantially raised by order of the Lord Chancellor since the war. But the analogy of the taxation of costs seems imperfect. A successful litigant is, if his opponent is solvent, able to recover his taxed costs. But it is notorious that he is lucky if he has not to pay substantial extras to his legal adviser which are not recoverable. Occasionally the order of the court, or the agreement of the parties, is that the successful litigant gets what are known as "costs as between solicitor and client"; this means that the litigant gets the whole of his expenses paid. On other occasions, however, when he is merely awarded ordinary costs, the

taxation of the lawyer's bill merely serves to prove that there is one (rather meagre) standard which the Taxing Master is officially prepared to approve as necessary and proper, and another (more generous) standard on which the solicitor actually charges his client.

The Use of Convicts for Cancer Experiments.

Dr. Norbury, medical officer of health to the Holywell Rural District Council, in a speech in support of the British Empire Cancer Campaign, is reported to have made the suggestion that condemned murderers should have the option of offering themselves for experiment. Research work, he said, is hampered for want of material; hanging a murderer is waste. The idea might not be seriously considered to-day but he predicted that posterity would be willing to give it a trial. It is elsewhere reported that the Cuban Board of National Sanitation has approved a proposal to inoculate convicts under death sentence with cancer germs for purposes of clinical study. The suggestion is apparently coupled with a time limit; if the convict agrees and submits himself, and if he survives 12 years later, what is left of him will then be set at liberty. It would, as has been pointed out, be interesting to see how public opinion reacted to the suggestion. Would it be regarded as a cruel or a humane proposal? And what is meant by "cancer germs"? The medical officers of prisons may find an increasing curiosity on the part of their patients as to the prospects of the artificial introduction of cancer.

It will be remembered that last week our Berlin correspondent reported¹ some medico-legal opinions on a proposal, emanating from Riga, to offer a reprieve to criminals who would submit to inoculation with leprosy bacilli.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Seizure of Quinine.

FOLLOWING the seizure by the Federal Government of quinine worth about £20,000 in New York warehouses, the Federal District Court in that city has entered a consent decree permanently enjoining further violations of the anti-trust laws by the interests that control the world supply of quinine. Production, distribution, and therefore the price of quinine have been absolutely controlled, it is said, by an international syndicate of Dutch, German, French, English, and American manufacturers. In the opinion of the U.S. Department of Commerce the monopoly has been "about as effective as there is anywhere." Henceforth manufacturers of quinine will be restrained from—

1. Imposing restrictions on the re-sale of quinine in the United States.
2. Hindering the shipment in, into, or from the United States of cinchona bark or quinine derivatives.
3. Participating in any arrangement for pooling or division of profits or territory with reference to sales made within the United States.
4. Discriminating between purchasers located within the United States.
5. Selling on condition that the purchaser will not deal with a competitor of the seller.

The Audiometer.

It is now about three years since the Western Electric Company produced the audiometer, a device for the measurement of auditory acuity. Essentially this consists of a gramophone from which the sound is reproduced through a telephone instead of through a horn. It is, of course, possible to attach as many earphones to the apparatus as are required to test a group of individuals all at the same time. Thus a class of, say, 40 school-children can all have their hearing tested in from 10 to 45 minutes according to

¹ THE LANCET, Dec. 8th, p. 1207.

salmonella group and many streptococci. The cattle were dirty and ill-kept, and it was thought the milk might have been infected through this polluted pond. Dr. Holmes reports that the registration of milk producers and vendors in the county is very incomplete.

The appointment of a whole-time rivers inspector has proved of immense benefit in preventing the pollution of rivers and streams. Another hopeful feature is that the various trades are taking a real interest in the purification of wastes. Both the beet-sugar industry and the gas engineers have formed a research committee, and a dyeworks and a colliery have installed apparatus for dealing with their wastes.

The Notts Nursing Federation have appointed 12 new district nurse-midwives for each of whom they received a grant of £30. Other nurses have been appointed to supply the needs of the new colliery villages. The county council have increased the number of health visitors from 20 to 25, but find a difficulty in filling the new appointments, and there were still three vacancies at the end of the year.

East Suffolk.

Dr. Bernard Wood-White reports that the problem of the pollution of the river Gipping by the waste of the Stowmarket silk works is still unsolved, and that attention is being drawn to the condition of the Stour, owing to the intention to use it for water-supply. During the first six months of the operation of the Housing (Rural Workers) Act 35 applications were received. Two were refused, and 19 grants were promised, totalling £788. With regard to "ribbon" building, Dr. Wood-White thinks that in a short time the traffic on the main roads will increase to such an extent that it will become the height of folly to build houses alongside them. The arterial roads should proceed as far as possible through uninhabited country, and avoid towns and villages for the sake of the quiet of the inhabitants and for the convenience of the traffic.

During 1927 six samples of milk examined at the county laboratory were found to contain tubercle bacilli. Four were complaints from Lowestoft, and two were from a group of 33 routine samples taken by arrangement with the district councils. In three cases tuberculous cows were found and slaughtered, but in the other three the biological tests could not be carried out owing to the shortage of guinea-pigs. There are no licences in the county as yet for Certified or Grade A (T.T.) milk.

Dr. Wood-White has extended his investigation of the economic loss caused by various diseases. During 1927 the following deaths occurred: heart disease, 385; cancer, 310; bronchitis, 172; tuberculosis, 153; influenza, 130. When the age value of the lives lost is considered, the comparative damage to the community from these deaths was in the following order—tuberculosis, 2827; cancer, 2702; heart disease, 1839; influenza, 1147; and bronchitis, 431. Dr. Wood-White also finds that the East Suffolk deaths from heart disease occur at higher ages than in the county boroughs and the rest of England and Wales, and he gives reasons for his opinion that acute rheumatism is less common in East Suffolk than in the rest of the country.

Cambridgeshire.

Dr. Frank Robinson reports that the need for a maternity hospital will be somewhat relieved by the opening of an eight-bed ward at Addenbrooke's Hospital, but it is hoped that ultimately a maternity home will be provided in the grounds of the hospital, supported by grants from both town and county, at which an efficient antenatal clinic will be established. The county council granted three nursing scholarships of £75 each during the year, and since 1913 it has, in this way, facilitated the training of 37 nurse-midwives. The county council also subsidises the County Nursing Association, and there are now only 26 rural parishes, with a population of 7700, without a nursing service. The first clean milk competition was held in the six rural districts which constitute the administrative county outside the

borough of Cambridge. Twenty-one herds, containing 596 cows, were entered. Of the 134 samples taken, 48 per cent. reached the standard of Certified and 68 per cent. the standard of Grade A milk. The judge commented that the competition showed that it was possible to train old milkers in modern methods. It is now becoming feasible to close unfit houses. Use was made of the Housing (Rural Workers) Act for two cottages only, and the county council sanctioned loans to the extent of £4650 under the Small Dwellings Act.

Huntingdonshire.

Dr. C. B. Moss-Blundell would like to see more stringent measures taken to deal with tramps, seeing that, in addition to damaging property by fires and pilfering, they act as spreaders of disease. The needs of the tuberculosis dispensary include a branch in the north of the county and a more systematic examination of contacts. The total deaths attributed to tuberculosis were 41, and the contacts examined numbered 67, of whom 20 were tuberculous, 10 doubtful, and 37 non-tuberculous. There were four notifications of, and four deaths from, encephalitis lethargica.

Holland.

Dr. H. C. Jennings's report has as a frontispiece a photograph of the Clean Milk Exhibit shown by the health department at the County Agricultural Show in June. Additions to the activities of the health department include a new branch tuberculosis dispensary at Donington, an infant welfare centre at Crowland, and the establishment of a county laboratory. There were six notifications of encephalitis lethargica, and five ended fatally. The notification of tuberculosis is unsatisfactorily carried out. The Holland Sanatorium (24 beds) is chiefly used for advanced cases, but the council also provides treatment in out-county sanatoriums (20 beds). In this county, where distances from the nearest medical practitioner may be great, the problem of the handy woman presents special difficulties. The solution lies, says Dr. Jennings, in forming many nursing associations with resident midwives. The necessary equipment has not yet been provided for the conduct of antenatal work at the welfare centres. There were only three applications under the Housing (Rural Workers) Act, of which two were withdrawn and one refused. There is a considerable amount of poor-law hospital accommodation in the county available for use on a voluntary basis.

Isle of Ely.

Dr. J. Pixton Walker reports that the new health offices were opened in October. He states that there is great difficulty in finding institutions willing to take mentally deficient cases from his area. There is a proposition for the purchase of a hall for the county of Norfolk for this purpose, and Dr. Walker hopes that his county will associate itself with this scheme.

Rutland.

Dr. Christopher Rolleston welcomes the Housing (Rural Workers) Act, 1926, as one of the most beneficent measures ever adopted. During the first six months of its operation four houses have been converted into satisfactory dwellings, but the benefits of the Act are as yet insufficiently known. Veterinary inspection of cattle is now in active operation in Rutland. Of the total deaths one-half were of persons over 65, and one-quarter of persons over 75. Dr. Rolleston points out that a large portion of the apparent increase in heart disease is due to the greater age at death and the fashion of certifying from "heart disease" rather than from "old age." He thinks also that the decline in the mortality from cancer of the tongue is partly due to the decrease in syphilis and partly to better attention being given to the teeth. He quotes approvingly the recent resolution of the British Medical Association with regard to periodical medical and dental examination. The nursing service has been extended, and there are now only three villages lacking it. Rutland comes

out well for the high proportion of contacts examined at the tuberculosis dispensary, and also for efficient ascertainment of mentally defective persons.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 1ST, 1923.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 189 (last week 199); scarlet fever, 2777; diphtheria, 1420; enteric fever, 34; pneumonia, 1099; puerperal fever, 49; puerperal pyrexia, 126; cerebro-spinal fever, 12; acute poliomyelitis, 6; acute poliomyelitis, 1; encephalitis lethargica, 22; dysentery, 6; ophthalmia neonatorum, 76. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified in the following 16 counties:—London, 4; Chester, 4; Derby, 19; Durham, 33; Essex, 5; Lancaster, 40; Leicester, 2; Northampton, 1; Northumberland, 14; Nottingham, 8; Soke of Peterborough, 3; Stafford, 8; Warwick, 1; Yorks, West Riding, 24; Glamorgan, 13; Monmouth, 10.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Dec. 4th-5th was as follows:—Small-pox, under treatment 20, under observation 2; scarlet fever, 2548; diphtheria, 2096; enteric fever, 16; measles, 65; whooping-cough, 352; puerperal fever, 14 (plus 8 babies); encephalitis lethargica, 75; poliomyelitis, 4; "other diseases," 12. At St. Margaret's Hospital there were 8 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 19 (0) from measles, 6 (1) from scarlet fever, 31 (10) from whooping-cough, 34 (5) from diphtheria, 55 (12) from diarrhoea and enteritis under two years, and 56 (11) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Reading, Birmingham, and Manchester. Newcastle-on-Tyne reported 6 fatal cases of measles, Liverpool 6, and Stockton-on-Tees 2. Fatal cases of whooping-cough were reported—3 each from Liverpool and Manchester. Liverpool also reported 3 deaths from diphtheria. Diarrhoea claimed 5 deaths each at Liverpool and Manchester, 4 at Middlesbrough, 3 each at Leeds and Hull. Deaths from influenza did not exceed 2 anywhere except Manchester 3 (and Glasgow 5).

The number of stillbirths registered during the week in the great towns was 296 (corresponding to a rate of 43 per thousand births), including 47 in London.

The Services.

THE ARMY MEDICAL ADVISORY BOARD AND THE ARMY MEDICAL DIRECTORATE CONSULTATIVE COMMITTEE.

It has been decided to reconstitute the Army Medical Advisory Board, with the Director-General, Army Medical Services, as President, the members of the Board consisting of four civilian members of the medical profession and the President of the Medical Board, India Office (ex officio), when matters concerning India are under discussion. The secretary will be the deputy assistant Director-General of A.M.D.1. The following are the terms of reference: To advise the Secretary of State for War on any question of policy, in connexion with Army Medical Services, on which he may desire to consult them. The four civilian members will be appointed by the Secretary of State. In the event of a vacancy occurring, a fresh appointment will be made by the Secretary of State on the recommendation of the remaining members of the Board. The ordinary meetings of the Board will be presided over by a chairman appointed by the Secretary of State from among the civilian members of the Board and nominated by the members in consultation with the D.G.A.M.S. The D.G.A.M.S., as President, may attend any meeting of the Board if, on account of the special problems to be considered, or for any other reason, he desires to do so, and will then take the chair. The Board will meet three times a year, but the civilian members may arrange additional meetings on notifying the D.G.A.M.S. through the Chairman. After each meeting

the conclusions of the Board will be reported to the D.G.A.M.S. and, after further consultation if necessary, by him to the Secretary of State. The Secretary of State will see all or any of the civilian members of the Board whenever he desires to do so, and the Board as a whole will have the right, after informing the D.G.A.M.S., of access to the Secretary of State.

The following have been appointed to the Board: President: Lieut.-General Sir Matthew H. G. Fell. Chairman: Hon. Major-General Sir Berkeley G. A. Moynihan, Bt. Members: Hon. Major-General Lord Dawson of Penn, Hon. Major-General Sir Cuthbert Wallace, Prof. D. P. D. Wilkie. Secretary: Major C. M. Drew, R.A.M.C.

It has been decided to appoint an ARMY MEDICAL DIRECTORATE CONSULTATIVE COMMITTEE constituted as follows: The Director-General, Army Medical Services, chairman; the Deputy Director-General, Army Medical Services, vice-chairman; six civilian members of the medical profession who hold instructional or other appointments at University centres or medical schools, and one civilian member of the Chemical Warfare Committee as members. The Secretary will be the Deputy Assistant Director-General of A.M.D.1. The following are the terms of reference: To advise the Director-General, Army Medical Services, as to: (a) The supply of candidates for the Regular R.A.M.C. and its reserves. (b) Post-graduate and other professional courses of instruction for R.A.M.C. officers. (c) Such administrative or professional questions as may from time to time be referred to it. The civilian members will be appointed by the Secretary of State, on the nomination of the D.G.A.M.S. They will normally serve for three years. Full meetings of the Committee will be held twice yearly, or as often as may be required, at the War Office. Other meetings may be held elsewhere as required. The chairman or vice-chairman and two members of the Committee will form a quorum for the transaction of business. The Secretary of State has approved the following appointments to the Committee: Chairman: Lieut.-General Sir Matthew H. G. Fell. Vice-chairman: Major-General H. B. Fawcett. Members: Prof. J. Barcroft, Lieut.-Colonel Sir Robert A. Bolam, Colonel Sir E. Farquhar Buzzard, Colonel T. R. Elliott, Captain J. Fraser, Colonel G. E. Gask, and Colonel A. E. Webb Johnson. Secretary: Major C. M. Drew.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are notified:—Surg. Comdrs.: H. D. Drennan to *Victory*, for Portsmouth Dockyard; C. Ross to *Vivid*, for R.N. Barracks, Devonport; F. J. Gowans to *Victory*, for Haslar Hosp.; J. A. Maxwell to *London*; A. B. Clark to *Revenge*; H. E. R. Stephens to *Pembroke*, for R.M. Infirmary, Deal; H. R. B. Hull to *Victory*, for R.N. Hosp., Haslar; R. H. McGiffin to *Nelson*; T. R. L. Jones to *Emperor of India*; and J. G. Danson to *President*, for three months' post-graduate course. Surg. Lts.: A. E. Kingston to *Marlborough*; T. G. B. Drawford to *Dryad*; T. L. Cleave to *Argus*; L. J. Corbett to *Queen Elizabeth*; A. S. Nicol to *Defiance*; J. K. G. Way to *Dartmouth*; W. J. Doody to *Birmingham*; and J. Mitchell to *Cleopatra*.

ROYAL ARMY MEDICAL CORPS.

Col. G. J. A. Ormsby, late R.A.M.C., retires on retd. pay. Lt.-Col. FitzG. G. Fitzgerald, from R.A.M.C., to be Col., vice Col. G. J. A. Ormsby, to retd. pay. The undermentioned Lt.-Cols. retire on retd. pay: Bt. Cols. A. E. Hamerton and J. Powell (and is granted the rank of Col.), and W. Bennett (and is granted the rank of Col.). Maj. P. Power to be Lt.-Col., vice Lt.-Col. FitzG. G. Fitzgerald, promoted.

ARMY RESERVE OF OFFICERS.

Lt.-Col. A. B. Smallman, having attained the age limit of liability to recall, ceases to belong to the Res. of Off. Capt. G. Marshall, from Supp. Res. of Off., R.A.M.C., to be Capt. Lt. W. F. Roper from Reg. Army Res. of Off., R.A., to be Lt., retaining his present seniority.

TERRITORIAL ARMY.

Col. J. H. Hunter resigns his commn. and retains his rank with permission to wear the prescribed uniform. Lt.-Col. (Bt. Col.) A. R. Moodie, from Gen. List, R.A.M.C., T.A., to be Col., and to be A.D.M.S. 51st (Highland) Div. Lt. R. McD. Cairns to be Capt. Supernumerary for service with O.T.C.: Lt.-Col. F. A. E. Crew, Univ. Contgt., Sen. Div., O.T.C., to be Bt. Col.

INDIAN MEDICAL SERVICE.

To be Capt.: J. Smith. To be Lts.: Makhan Singh and Marinho De Azavedo. To be Second Lt.: J. Mackie.

Correspondence.

"Audi alteram partem."

THE MODE OF EXPRESSING THE DIFFERENTIAL LEUCOCYTE COUNT.

To the Editor of THE LANCET.

SIR,—I have long marvelled that so many pathologists are content to report their differential leucocyte counts merely in percentage form, and that clinicians are willing to put up with this. For nearly 30 years I have been accustomed to impress upon the students at St. Bartholomew's Hospital that, if they would understand the meaning of such counts, they must apply the percentage figures to the total count, and learn to think in terms of absolute figures of each kind of leucocyte per c.mm. of blood.

The recipient of a mere percentage count must, even if unconsciously, go through some such mental process before he can grasp the significance of the figures. When he is told that a patient has 60 per cent. of lymphocytes, he must necessarily pause and think for a few moments whether the increase is real or only apparent. Whereas if he is told that there are 2000 or 6000 lymphocytes per c.mm., he should apprehend the facts at a glance. In ordinary life we should not tolerate this roundabout mode of stating facts.

Not long ago you published in your series on the Clinical Interpretation of Aids to Diagnosis some excellent articles by Dr. S. C. Dyke on the interpretation of blood counts, and it is the article in your issue of Nov. 10th last which has moved me to these remarks, because it contains no reference to the direct way of expressing results. Dr. Dyke is very well aware of the fallacies which may lie on the face of a mere percentage statement; he felt obliged to draw attention to them here and there, and to explain that "relative lymphocytosis" practically always meant polymorphonuclear leucopenia. Yet it never seems to have occurred to him to tell his readers that by a plain statement of actual numbers all misconceptions could be avoided. When that is done we shall cease to hear the fatuous term "relative lymphocytosis"—fatuous because in so far as it is really relative it is not lymphocytosis. Dr. Dyke will then tell us, correctly, that eosinophilia means an increase in the total circulating leucocytes, not that it is an increase in their percentage number. The clinician himself will find it less trouble, in the long run, to learn once for all the normal numbers of each kind of leucocyte per c.mm., than to do sums in his head whenever he receives a percentage statement.

I am, Sir, yours faithfully,

Highgate, Dec. 8th, 1928.

F. W. ANDREWES.

A SIMPLE MECHANICAL AID TO LABOURED RESPIRATION.

To the Editor of THE LANCET.

SIR,—I should like to call the attention of my colleagues to a simple expedient for easing respiration in cases of dyspnoea. Anyone who has tried to breathe deeply when lying on his back will have noticed a certain inhibition at the end of inspiratory effort. If now the experimenter takes a towel folded to about a handbreadth, or any similar broad soft girdle, lays it against the small of his back, brings the two free ends forwards, and draws upon them so as to give support to the back, he will notice that his breathing becomes easier and the difficulty at the end of inspiration is removed. Obviously this result is likely to be better when the manipulation is made by a third person. The simple manoeuvre produces some alteration in the circulation with a certain definite relief to the right heart. It should find its use in many of the cases of respiratory or

circulatory disturbance, whether of functional and organic nature, which are seen in private work. The small of the back may also be supported by some arrangement in the bed, so that the effect can be kept up for a longer time, but its continuous application will only seldom be necessary. Intermittence several times a day seems to be advisable, and this should be gradual, not sudden. In pulmonary cases the pull on the side of the affected lung should be carefully controlled, especially if there is pleural effusion. That this owes its value not solely to suggestion has been shown by myself and my colleagues in a series of cases, but what exactly is the mechanism must be determined by exact experiment.

I am, Sir, yours faithfully,

Vienna, Dec. 3rd, 1928.

BERTHOLD BEER.

ULTRA-VIOLET LIGHT AND CANCER.

To the Editor of THE LANCET.

SIR,—In reply to the letter of Dr. M. Weinbren in your issue of Dec. 8th:—

1. The literature cited from Unna (1896) to Colquhoun (1927) shows that clinicians have with increasing precision incriminated first exposure to the weather, then prolonged exposure to sunlight, and finally therapeutic exposure to the mercury-vapour lamp in the production of certain precancerous and cancerous lesions.

2. A mercury-vapour lamp was not used to prove the effect of sunlight.

3. There was no relation between ulceration and the subsequent growth. The growth occurred on skin which either appeared normal or atrophic.

4. There was evidence that a slight degree of tolerance was acquired.

5 and 6. Experiments are already being carried out on the lines suggested.

7 and 8. Experiments with a thermophile show that under the experimental conditions used the rise in temperature is not greater than 5° C. Exposure of mice to a considerably higher temperature than this for eight months has up to the present failed to induce cancer.—I am, Sir, yours faithfully,

G. M. FINDLAY.

Imperial Cancer Research Fund, Queen-square, W.C.,
Dec. 8th, 1928.

CHRONIC SPASMODIC AFFECTIONS OF THE COLON.

To the Editor of THE LANCET.

SIR.—In Dr. Ryle's instructive paper mention was made of a few cases in which rectal pain was described. I have notes of two such, possibly worthy of publication. Both were males of lean appearance, intelligent, and not neurotic, whose symptoms were closely similar, and first noticed shortly after puberty. As exciting causes of pain were mentioned constipation, cold, and coitus. As regards the first of these, I incline to the belief that the hard, constipated motion resulted from the attack, for neither patient suffered normally in this manner, and inability to evacuate invariably followed, rather than preceded, the spasm. Sitting on a cold or hard seat was a potent exciting factor, but pain immediately following on the completion of coition was the symptom which eventually led both to seek advice.

In one, whom I examined in an attack, I found a hard, tender, and contracted colon in the left iliac fossa and, on introducing the finger into the rectum, great resistance was met owing to a similar spastic condition there. A second finger was introduced and lateral pressure exerted. The first result was aggravation of the pain which suddenly gave place to complete comfort coincidentally with relaxation of the affected segment. It is of interest to note in this connexion that the patient had discovered that a similar action on his part was the only certain means of abolishing the spasm. The pain itself was likened

to severe toothache, rapidly rising to its maximal intensity, and located deep to the sacrum and in the left iliac fossa. Its severity was described as almost unbearable, but it rarely lasted longer than ten minutes, and then disappeared completely in 30 seconds.—I am, Sir, yours faithfully,

London, W., Dec. 8th, 1928. A. H. DOUTHWAITE.

To the Editor of THE LANCET.

SIR,—In two previous publications (which have apparently escaped the notice of Dr. Ryle) I described the spastic conditions of the colon, accompanied or not by myxorrhoea, as syndromes of hypertonus of the parasympathetic centra of the colon. There are two distinct parasympathetic centra for the colon. The lower represented by a column of parasympathetic cells, situated in the first four segments of the sacral medulla, gives rise to the nervus pelvici, and through it innervates the left colon. The superior centre is in the nucleus of the vagus itself and innervates the right colon, that is the ascending and the greatest part of the transverse. Right and left colon are two distinct organs, with distinct functions, a different embryological origin (the left colon derived from the hind gut, and the right colon from the mid-gut), and a separate innervation. These colon parasympathetic centra have intimate connexions with the central nervous system and with the cortex itself, and this explains the central nervous and even the cortical influences.

The over-stimulation of the colon parasympathetic centra is due: (a) to humeral or endocrine factors acting on these centra; (b) to abnormal nervous impulses coming from the diseased colon itself—cancer or colitis; (c) to abnormal nervous impulses coming from any other diseased organ; (d) to abnormal nervous impulses coming from the central nervous system and therefore often from cortico-psychical disturbances.

For the accurate diagnosis of conditions of spastic colon, a thorough understanding of this mechanism is absolutely necessary, and therefore a precise knowledge of visceral neurology. I avail myself of this opportunity to plead for a rapid re-edition of the standard work on Visceral Neurology, Langley's "Autonomic Nervous System," which, unfortunately for the students of internal diseases, has been for a long time out of print.

I am, Sir, yours faithfully,
Wimpole-street, W., Dec. 7th. A. P. CAWADIAS.

THE RODS AND CONES.

To the Editor of THE LANCET.

SIR,—An annotation under this heading in your last issue contains a comment on my theory of vision. When I propounded this theory at two international congresses not only was there no dissent but the most emphatic approval. All the facts point to the conclusion that vision takes place by stimulation of the cones of the retina through photo-chemical decomposition of the liquid surrounding them which is sensitised by the visual purple. The rods are not percipient elements, but control the visual purple. Helmholtz stated that there was no evidence that the rods were percipient elements. This theory explains numerous facts which are otherwise inexplicable, such, for example, as the change in position in the field of vision of after-images on movement of the eye. Two after-images may combine into one, or a red after-image may go right through a green one. This proves conclusively that the stimulus is light.

Apart from the numerous facts against the duplicity theory, which supposes that the rods are percipient elements for perception in a dim light, it will be found that it is supported almost entirely by misstatements—namely: (1) that certain animals have only cones and others have only rods; (2) that the periphery of the retina is colour-blind; (3) that the eye is totally

colour-blind in dark adaptation; (4) that the Purkinje phenomenon and the recurrent image are not found with the fovea. With regard to these I offer the following criticisms.

1. Though I have examined numerous collections I have never been able to find any animal with only rods or only cones, neither have I found anyone who has seen such a retina. The tortoise is the most quoted; it is stated to have only cones. The rods and cones in the retina of the tortoise are as clearly defined and distinct as in the human retina.

2. The periphery of the retina is not colour-blind when colours of sufficient intensity are used. The reader can test this for himself with a doctor's red lamp. He will find he can see it as red to the extreme periphery.

3. In dark adaptation the eye is not totally colour-blind. Further, there is no scotoma or blind area corresponding to the rod-free portion of the macula which is equal to a visual angle of about three degrees.

4. The Purkinje phenomena and recurrent image are found with the fovea. Hess showed not only that the recurrent image was found with the fovea, but also that it was bent outwards at this region as it would be if the visual purple had to flow into the fovea.—I am, Sir, yours faithfully,

London, Dec. 8th, 1928. F. W. EDRIDGE-GREEN.

SMOKELESS FUEL AND PUBLIC HEALTH.

To the Editor of THE LANCET.

SIR,—A letter under the above heading appears in your issue of this week. Besides being of great benefit for public health, low temperature carbonisation of coal should, if carried out to the extent necessary, bring at least some prosperity to the mining areas. With regard to the efficiency of it, I can speak from experience, as for the past six months I have had no coal in my house, and have been burning a fuel prepared by low temperature carbonisation, and with great success. It is as easy to light as the best coal, gives a hot and bright fire, no trouble with the flues, and a hot oven. In fact, since using it, we have had a far better cooking oven than with coal.

We are a conservative nation, and it takes a good deal to alter our ideas, and it is so with the use of coal; but once the process gets into full swing and the fuel is readily obtainable at a reasonable price, no one who has given low carbonisation fuel a fair trial will want to return to the use of raw coal.

I am, Sir, yours faithfully,
F. L. NICHOLS.

Fulbourn, near Cambridge, Dec. 8th, 1928.

A TUDOR ACT OF INDEMNITY FOR UNQUALIFIED PRACTICE.

To the Editor of THE LANCET.

SIR,—Mr. Fred Bullock has given good reason for the sudden attack on the surgeons as a body by showing that it was in some measure due to the unwise exercise of their jurisdiction over unlicensed practisers of surgery. He has also given the correct meaning of certain mediæval medical terms mentioned in the Act. By the way, is the Romney document a copy of the Statute, or is it a Proclamation? I ask for information. But there are other factors which give the subject a wider interest—e.g., the principles which guided Henry towards the regulation of the medical profession. Educated for the Catholic hierarchy when, by the solicitation of his ministers, he was urged in the third year of his reign to regularise the profession of physic he gave to the Church the dominating power. By the Act (3 Henry VIII., c. 11) he ordained that no person within the City of London and seven miles should take upon himself to practise as a physician or surgeon except he be first examined, approved, and

admitted by the Bishop of London or Dean of St. Paul's calling to him four doctors of physic, and for surgery other expert persons in that faculty. Outside the City and environs similar powers were given to the bishop of each diocese or his vicar-general, in like manner calling to them expert persons; the privileges of Oxford and Cambridge Universities being safeguarded. Six years later (1518) at Wolsey's instigation, persuaded thereto by Linacre, Henry founded the College of Physicians by Royal Charter, whereby the power given to the Church by the previous Act was transferred, so far as the practice of physic in London was concerned, to the College. This charter was confirmed by Act of Parliament and enlarged in the following, among other, particulars. In the dioceses outside London it had been found difficult to procure men able sufficiently to examine candidates, and consequently it was enacted that no person should be allowed to practise physic throughout England, without examination and approval of the College. The Bishop of London, as well as the others in their respective dioceses, continued to license in surgery, but in London the practice had proved unsatisfactory. The surgeons were few, they were for the most part illiterate, and if we are to believe the preamble to the Act (34 Henry VIII., c. 8) they were grasping and unscrupulous.

Physic had been dealt with to Henry's satisfaction; for the good of his people his attention was drawn to the insufficiency of surgical knowledge. There were at this time two several and distinct companies of surgeons practising surgery in London, one large and influential, the Company of Barbers incorporated by Edward IV., the other, the Company of Surgeons, small, needy, and not incorporated. For the better control, exercise, and knowledge of surgery Henry deemed it expedient that these should be joined together as the United Company of Barbers and Surgeons of London (1540). By their charter they were empowered to govern the practice of barbery and surgery in London; the barbers were henceforth restricted to barbery—i.e., washing, shaving, and the drawing of teeth, and were forbidden the letting of blood or any other thing belonging to surgery; the surgeons were similarly forbidden to practise barbery.

As Mr. Bullock shows, the surgeons became arrogant, making unreasonable use of their monopoly by prosecuting those who had ministered to the wants of their neighbours without gain. To mitigate the rapacity of the approved surgeons who, "minding only their own lucre and nothing the profit of the diseased or patient, will do no cure without knowing that they will be rewarded with a greater sum or reward than the cure extendeth unto," the Act (34 & 35 Henry VIII., c. 8) took its place upon the Statute Book. In it the right was given to any person with knowledge of barbery, &c., to use ointments and plaisters to any outward sore, swelling, or disease, and to administer drinks for the stone and strangury, or agues, without penalty, any other Act to the contrary notwithstanding. The internal administration of medicine for all and every other disease came within the monopoly of the physician, himself entitled to practise surgery as well as physic. The Act of 1542-43 has been called "The Quack's Charter"; it is still unrevoked.

When Henry threw off the domination of Rome he recognised that, as it had been the custom of the Popes, through their legates, to confer extra-territorial degrees in theology, law, and physic, unless he provided for the continuation of the ecclesiastical prerogative, appeals would be made to the Roman Pontiff for such degrees. He therefore by Act of Parliament ordained that the Archbishop of Canterbury should have the power to grant certain faculties; these became known as the Lambeth degrees, which are still bestowed upon chosen candidates under this Act. But the M.D. Lambeth does not now of itself confer the right to practise medicine.

I am, Sir, yours faithfully,

GEORGE C. PEACHEY.

Randolph-crescent, W., Dec. 1st, 1928.

WHAT IS A BAD RADIOGRAM?

To the Editor of THE LANCET.

SIR,—I have read with interest the leading article in your issue of Nov. 24th entitled *What is a Good Radiogram?* and I agree with its assertions. At the same time it does not quite define the good radiogram. May I help by trying to define the bad radiogram?

A bad radiogram I would define as one which does not render the viscus it is supposed to portray to full advantage. It is not sharp or clear. It may be ill-defined owing to over or under exposure, over or under development, or one of several combinations of the above. All these factors may be correct, but the accelerating screen so faulty as to render the negative poor. The greatest of all faults is that the bad radiogram is taken, whilst the good one is made. By "taken" I understand that a film is placed on one side of the patient, and exposed to X rays, showing on it whatever presents itself at the time, and as it lies in the given position. On the other hand, the word "made" signifies that steps have been taken to make the film of diagnostic value, and that the correct time is chosen to render a given viscus at a stage when it is best filled. It is then to be shown on a "cleared deck," or so that superimposing coils of bowel are dispersed by angulation, gravity, or pressure by inopaque object, during the exposure, to reveal the part one wishes to show; or again, efforts are made to bring movable parts out of the pelvis by manipulation, then pinned down during the exposure, and thus the diagnostic value of a radiogram is enhanced. The original lie of the same viscus can be expressed in a statement, for instance, "caecum, terminal ileum and appendix huddled up in pelvis."

And, secondly, a radiographic report may be successfully executed, and yet the diagnosis may be missed owing to faulty judgment. For this reason I feel guilty of neglect in every negative X ray report issued—guilty of errors of omission and too fixed technique, omission to observe carefully or demonstrate each viscus in many angles, omission to observe or demonstrate the site of each viscus in turn soon after clearance, to look for opaque spots which when found can be followed up and placed. Want of elasticity in the times of investigation can be the cause of bad radiographic reports, for instance, an appendix may be shown partly filled at eight hours, partly empty at 24, yet at intervening stages it would have presented full. Such an error of judgment produces two misleading radiograms.

Finally, I would like to say that you can put heads together by the score over a well-executed negative radiogram, only to waste their time, because it is faulty in judgment—when (say) 10 degrees of rotation would have revealed the evidence of a gross lesion.

I am, Sir, yours faithfully,

O. A. MARNER.

Ruthin Castle, North Wales, Dec. 3rd, 1928.

ROYAL NORTHERN GROUP OF HOSPITALS. — This group held a festival dinner on Dec. 5th at the Savoy Hotel, with the object of collecting £10,642 to complete the sum of £35,000, which an anonymous donor has promised to double when it is attained, in order to erect a block of pay-beds. Lord Bearsted, who took the chair, proposed "Success to the Hospital." He explained the position and surveyed the work of the Royal Northern Hospital, where the new block will be erected. The Marquess of Northampton appealed to local employers to encourage their workers to use the Contributors' Certificates scheme, by which receipts for donations are accepted as cash for treatment within ten years of their issue. Major Sir Archibald Boyd-Carpenter, proposing "The Voluntary System," suggested that the large motoring associations should approach their members to give a weekly contribution. The Rev. Basil Bouchier supported, and the Rt. Hon. H. J. Tennant responded. The health of the chairman was proposed by Mr. L. E. Barrington-Ward, and seconded by the Lady-Amherst of Hackney. The secretary announced that the subscriptions to the festival totalled £13,134.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT (SCOTLAND) BILL.

In the House of Commons on Wednesday, Dec. 5th, the House went into Committee on the financial resolution in connexion with this Bill. Mr. JAMES HOPE was in the chair.

Major ELLIOT (Under Secretary of State for Scotland), in moving the resolution, said that in Scotland the total local government expenditure was £33,000,000, and was at present something in the ratio of £13,000,000 from grants and £20,500,000 from rates. After this Bill had gone through the proportion between rates and grants would be something like £16,000,000 from grants and £17,000,000 from rates. First of all it was proposed to sweep away the assigned revenues, and so on, and create a general Exchequer contribution which would be fed annually by such grants as Parliament might determine. Secondly, this grant would be further fed by a sum to compensate for the de-rating grants and for discontinued grants. The third point was that this grant would be revised quinquennially. The fourth point was that the grant would be to maintain a given ratio permanently between the total rate and grant-borne expenditure. That was to say, that in the future there would be a ratio preserved between the money coming from the Exchequer and the rate-borne expenditure which was a variable one. Therefore the Exchequer contribution was also variable upwards. There was a guarantee against varying downwards. The fifth point was that the grant should deal with what were called necessitous areas by being distributed according to needs and abilities, and it dealt with the question of necessitous areas in the widest possible sense. As regarded the distribution of the General Exchequer contribution the principles of the scheme were the same in both England and Scotland.

The Labour View.

Mr. WILLIAM GRAHAM, speaking for the Labour Party, said that whatever might be the problems of local finance in Scotland they were aggravated beyond description by this Bill and by the undeniable confusion that it would introduce. The Labour Party had always pleaded that it was altogether unjust that the structure of the poor-law in Scotland, which was never designed to carry a load of this description, had had to obtain in the aggregate from the ratepayers in all parts of the country millions of money since the industrial depression began. There was every reason in the world for the plea of the Labour Party that this should be made a national charge. The transfer would be followed by far-reaching and impressive results. The question for Scotland as for England was whether there was any real merit in the block system of grants as opposed to the percentage system. The burden of the attack upon the percentage system had been that under it the Chancellor of the Exchequer of the day did not know what exactly he had to contribute to those local services year by year. There was no foundation for that argument, as the financial machinery of the House provided for review and free determination of the estimates dealing with those grants. Moreover, no one had ever suggested that there had been any waste or misdirection by the Scottish local authorities in expenditure under the percentage grant system. Having regard to the fact that the aggregate burden of the local rates in Scotland had bounded up until they were now £22,000,000, the proportion borne by the local authorities was so exceptionally high as to secure economy in the local services. He recognised that it was no use meeting the Government plan with a blind negative. They could easily mark off and arrange areas which could be treated specially as necessitous. By the Government scheme all kinds of fresh anomalies and new problems would be created in the necessitous areas. In a matter of this kind what they had to look to was a broad transfer from national funds and the extent to which such transfer would operate during the next 10 or 15 years. At the very heart of this problem there was the question of the funds to be provided to meet the necessary expansion of local services. If any new duties were imposed on the local authorities in Scotland they should clearly understand there was no real provision in the Government scheme of assistance from the Exchequer to meet the increased expenditure involved.

Development of the Public Health Services.

Dr. DRUMMOND SHELS said that he was very disappointed that the Under Secretary of State for Scotland had omitted to make any comment upon, or to give any justification for, the proposed change in the method of financing public health services by bringing them into the ambit of a block grant instead of allowing them to continue under the

percentage grant system. This was one of the most important matters in the Bill. The percentage grant system has been criticised on the ground that the more a district spent the more it got, but he thought that the Government would agree that in Scotland there was as yet no town or country district which had a really adequate public health system, or in which an excessive amount of money had ever been spent upon it. As a matter of fact they were not really abolishing the percentage grant system in Scotland. The portion which was to be included in the block grant was an infinitesimal part of the total sum, the bulk of which was still to be paid under the percentage grant system. It was a remarkable thing that the health services should be the one thing that had been put under the block grant system. The public health services were the most rapidly developing of all public services. He wondered whether that was the reason why those services had been selected for the change. He believed that the Minister of Health and the Secretary for Scotland were not unsympathetic to the development of the health services, but he strongly suspected the Treasury, which, as they knew, was a very powerful influence behind this Bill. Public opinion was ripe for a still larger development of these services. In many of the large towns in Scotland this year and the preceding year had been economy years, and yet this year was the one which was to be taken as the standard year, and if any development of the services now in existence were undertaken within the next five years it would mean that the expense would fall on the ratepayers and would have to be borne by a much smaller number of ratepayers than at the present time. That was a serious position. The hon. Member for Caithness and Sutherland (Sir A. Sinclair) had called attention to the fact, which was of great importance, that in his own county there was no maternity and child welfare service, and they knew that a number of other districts in Scotland were in the same position. Was it expected that any district which had no maternity and child welfare service at the present time was likely to establish one within the next five years, seeing that to do so would involve a very great increase in the local rates? There were figures to show that in Edinburgh last year in the case of mothers who had been given antenatal treatment there was a much lower percentage of mortality than in the case of those who had not been so treated. The figures showed that there were something like four or five times the number of deaths among those who had had no antenatal treatment as compared with those who had been previously attended. The importance of that was being realised, and in those cases where the service was not very adequate there was room for development, while in certain cases it had not been taken up at all. Was it likely that that would take place under this system of block grants? He asked that if the whole of the public health services could not be taken out of this block grant, that maternity and child welfare should at least be excluded from its operation and remain under the percentage grant. For a number of years past the House and the Scottish Board of Health had put upon local authorities various new duties, some of them small and others very extensive. It was likely that in the next five years something of the same kind would take place. Not very long ago there was insulin, which the local authorities now had to supply, and there was a new duty imposed in regard to encephalitis. Under the Government's scheme localities would have to wait for five years before putting such developments into operation, or would have to put on the rates the whole expense of services which the House or the Scottish Board of Health might call upon the local authority to provide. It was obvious that some arrangement to meet that position should be made.

Block Grants v. Percentage System.

After further debate,

The LORD ADVOCATE (Mr. WILLIAM WATSON), dealing with the contention over the rival advantages of the block system of grants and the percentage system said that the main objection to the latter system was that under it the richer districts had a free hand in expenditure and the poorer districts were penalised. That was a very vital point, especially when they were considering the adequate development of, among other things, the health services. It was urged that the central authority should bear the whole burden. But the local authorities had some liabilities, and to expect the central authority on every occasion to be the person who was going to pay the extra expenditure, in the case of the poorer districts the whole of the expenditure, was going too far. The question was: What was a fair proportion, and what was the fairest method of getting that proportion? The Government said that the block grant system was the fairer method of the two. They were just as determined in Scotland as the Ministry of Health was in England to see that maternity and child welfare services were fully protected and carried out.

The resolution was carried by 224 votes to 140—majority 84.

Medical Members and Local Government Bill.

At a meeting held at the House of Commons on Tuesday, Dec. 11th, attended by medical Members of the House, and by a deputation representing the British Medical Association, the medical aspects of the Local Government Bill were very fully discussed. It was decided that Lieut.-Colonel Fremantle and Sir Richard Luce should bring forward certain amendments designed to strengthen the Bill, but on the whole the deputation was understood to give general approval to the main provisions of the measure in regard to health matters, subject to confirmation by the Council of the Association at their meeting on the following day. An amendment, to which great importance was attached, will propose that the power given to a council under Clause 4 to deal with non-desstitute as well as destitute persons by means of the health services which they provide under a series of Public Health Acts enumerated in the clause shall be made mandatory instead of permissive.

"Guillotine" Resolutions.

The House of Commons considered on Tuesday, Dec. 11th, a "guillotine" motion setting up a time-table for the subsequent discussions on the English and Scottish Local Government Bills. After several hours of debate it was decided to allot 17 days for the further stages of the English Bill divided as follows: Committee, 13; report, 3; third reading, 1. For the Scottish Bill 12 more days were allotted, divided as follows: Committee, 9 (one more than originally proposed); report, 2; and third reading, 1.

THE DISTRESSED AREAS.

On Wednesday, Dec. 5th, on the motion for the adjournment,

Miss WILKINSON called attention to the urgent need for clothing for the children in the necessitous areas, and asked whether it would be possible for the Government to give a Treasury grant.

Lord EUSTACE PERCY (President of the Board of Education) said that nothing he could say could exaggerate the extreme seriousness of this problem, but need they say that voluntary effort had so far failed to do its part of the task that it must be taken over as a State matter? In South Wales so far as nutrition was concerned the difficulty was that the cost of the food given to school-children was deducted from the poor-law relief given to the parents; but an agreement had been reached with the guardians that no deduction was to be made. Over the whole of Glamorgan the feeding of school-children was proceeding on the basis of medical selection, and in the Rhondda over 1000 children were being fed after medical certification. He sent down a medical officer a few weeks ago to look into the question of whether the standard applied was too stringent, and the report which he received was to the effect that the work was being thoroughly well done and that the ground was being covered, but that it was necessary that the medical inspection should be continued. That was being done at the present moment. His reports were that serious deterioration among children was being prevented. The question of Government assistance in relief of the distress was one which had to be, and would be, considered.

HOUSE OF LORDS.

THURSDAY, DEC. 6TH.

PROTECTION OF ANIMALS (AMENDMENT) BILL.

On the motion that the House do now resolve itself into Committee on the Protection of Animals (Amendment) Bill,

Lord DESBOROUGH said that he wished to explain at that stage the position of the Government in case at future stages of the measure any silence on their part might be misinterpreted. On the second reading he had done his best to show that the Government were not at all enthusiastic about it, and that they considered that its provisions were not of a workable character. Lord Banbury had had more than one interview with the Home Office and he was sorry to say that he had not been successful in removing the objections which they previously entertained. No complaints had been received by the Home Office that Section 3 of the Protection of Animals Act, 1911, had not worked satisfactorily up to the present, and it was the view of the Home Office that the present Bill could not be amended so as to make it a workable measure.

Earl RUSSELL said that it would be a waste of time to ask their Lordships to go on with a Bill which the Government had told them was quite unworkable. He therefore moved that the debate be adjourned.

Lord BANBURY, who was in charge of the Bill, said that the Under Secretary to the Home Office (Sir Vivian Henderson) had informed him on the previous day that the

Home Office did not intend to oppose this Bill. He therefore suggested that their Lordships might pass the Committee stage, and if the Home Office had changed their minds before the third reading the House could then take what action they thought right.

After further discussion the motion to adjourn the debate was agreed to.

PRESERVATION OF INFANT LIFE BILL.

The House went into Committee on this Bill. The Earl of DONOUGHMORE was in the chair.

Punishment for Child Destruction.

Clause 1 of the Bill provides:—

(1) Subject as hereinafter in this subsection provided, any person who, with intent to destroy the life of a child capable of being born alive, by any wilful act causes a child to die before it has an existence independent of its mother, shall be guilty of felony, to wit, of child destruction, and shall be liable on conviction thereof on indictment to penal servitude for life: Provided that no person shall be convicted of an offence under this section if it is proved that the act which caused the death of the child was done in good faith for the purpose only of preserving the life of the mother.

(2) For the purposes of this Act, evidence that a woman had at any material time been pregnant for a period of 28 weeks or more shall be prima facie proof that she was at that time pregnant of a child capable of being born alive.

Lord ATKIN moved to leave out Clause 1 and to insert the following new clause:—

(1) A woman may be convicted of infanticide notwithstanding that the death of her child is caused by her in the course of delivery; and the term "newly born child" in the Infanticide Act, 1922, shall include a child while in the course of delivery.

(2) For the purposes of this Act the course of delivery shall be deemed to continue until the child has an existence independent of its mother.

He said that when the Bill came before the House for second reading he took objection to it upon the ground that it went much farther than was necessary and that in particular it exposed professional men to the danger of being charged with an offence which was a new offence, and one which it was unnecessary to put upon the Statute Book. He was prepared to admit that the present gap in the law ought to be remedied, and his amendment did in terms precisely provide for that position. The amendment proposed that instead of the new offence being created the offence of infanticide should be extended so as to include the case of the killing of a child by the mother in the course of delivery. The Bill as it stood went much farther than that in two particulars. In the first place it extended the offence to third persons other than the mother. He knew of no cases in which it had ever been suggested that there was a deliberate act of killing a child in the course of delivery, unless it was by a doctor or a midwife. From the nature of things it was practically impossible that there should be anyone else capable of killing the child during birth. He was very reluctant that a new offence should be created which would comprise professional men and professional women—because midwives now had to be licensed—and which could expose them to the possibility of a charge of this kind. It happened from time to time that the doctor had to make up his mind that in order to save the mother's life the child must be sacrificed. This Bill in the terms of it would make such a doctor liable to a new offence punishable by penal servitude for life unless he discharged the onus of showing that he did it in good faith for the purpose of preserving the life of the mother. He objected very strongly to any onus being put upon anybody to prove that he was innocent, and he thought it was very inadvisable that a new offence should be created under which professional men and women would carry on their very important vocations with a possibility of a criminal charge being brought against them, either by a disappointed parent or a mischievous attendant. He had made inquiries and he had not come across a single instance in the whole history of the administration of the criminal law where it had been suggested that there had been an improper act done to a child by a third person other than the mother in the course of birth. Under the present law coroners had the duty to hold inquiries on the births of children, including stillbirths, and he knew of no case where in such circumstances any suggestion had been made that any third person had committed an offence. It was quite sufficient to meet the only evil to which attention was originally called—namely, the case where a mother was supposed to have killed her child in the course of delivery. There was another provision in the Bill which was objectionable; that was that the offence was not confined to the killing of a child in the course of birth, but was extended to the killing of the child before delivery had begun, while it was still in the body of the mother, and she was still pregnant. That was an unnecessary proposal, because it

would overlap the existing law as to procuring abortion. The practice of abortion was very rife in these days, and caused where it was successful untold pain and suffering and in many cases death. The present law as to abortion provided that any person who used any means, either instruments or any other, with the intention of procuring a miscarriage, committed an offence which was punishable by precisely the same punishment as was provided in this Bill—namely, the maximum punishment of penal servitude for life. He was advised, and had found it to be so in books of authority upon medical jurisprudence, that it was really impossible to kill a child in the body of the mother without procuring a miscarriage, and without therefore obviously intending to procure a miscarriage as the natural result of the action taken. In that respect the provision in the Bill was unnecessary, and indeed was undesirable, because it weakened the law as to abortion by narrowing it and by creating an offence which required that there should be an intention to kill the child; whereas it was not necessary in the ordinary law as to abortion. He hoped that their Lordships would limit the scope of the Bill, because as it stood it was very undesirable from the point of view of the medical profession and the nursing profession.

A Grave Offence.

Lord MERRIVALE said that why Lord Atkin should be ready to leave one branch of this class of offence to be a felony, punishable by penal servitude for life, and as to the major area should say it was sufficiently dealt with by a slight provision creating a new misdemeanour, passed his comprehension. The offence was a most grave offence. There were aspects of the crime of abortion with regard to the living person and with regard to the unborn child which it was not necessary to dwell upon, but which emphasised the gravity of the matter. Lord Darling had framed a Bill which was accepted in principle by their Lordships' House and then sent to a Select Committee. All that the Bill was designed to do was to provide that in the case unprovided for the penalty of abortion should be incurred by those who were engaged in the act. That seemed to be entirely consistent with the policy which had been pursued in our judicial administration. He had great difficulty in seeing how this grave offence could be guarded against, in this particular in which there was almost an invitation to criminally minded people to take the action they were so ready to take, until they put the law on an even footing. Lord Atkin had been concerned about the effect of the proposals in respect of the liability of medical practitioners and registered midwives. He (Lord Merrivale) said that all due effect should be given to that legitimate concern. No self-respecting person, no person of any experience, wished to imperil a decent doctor who had performed a terrible task and had deprived a fellow creature of life. No one wished that he should be lightly exposed to criminal proceedings. But it was not the respectable medical practitioner who ran this risk, or the decent midwife; it was the people who at the present time practised abortion, and who in a vast number of cases escaped without any penalty because it was a crime most difficult to bring home to those who were guilty of it. He would regard it as a mockery to pass a Bill through that House which left the people who provided the means for this crime, and actually put it into effect, free of risk, and put such penalty as might be incurred upon the unhappy woman who for money they involved as an accomplice in a criminal transaction. It seemed to him that their Lordships would abundantly provide for the security of the respectable medical practitioner and the respectable midwife if a clause or subsection were inserted which provided that there should be no prosecution of a registered medical practitioner or a registered midwife without the sanction of the Attorney-General. He hoped their Lordships would not accept the amendment of Lord Atkin.

Lord PARMOOR said that it was a matter of very great importance that in questions of this kind they should not make the law harsher than was absolutely necessary in order that the crime might be suitably punished both as a deterrent and as a punishment in a particular case. The Bill as it stood was unduly harsh, and if Lord Atkin pressed his amendment to a division he (Lord Parmoor) would vote for it.

An Uncontrolled Evil.

Lord DARLING said that the amendment was only a new method of doing what the noble lord attempted to do when he moved the rejection of the Bill. The amendment if carried would leave a great part of the evil which the Bill attempted to prevent absolutely uncontrolled. It would deal with the case where a woman in labour purposely killed the creature before it had got a separate existence, and with that alone, and it would say that that offence was nothing more than an offence of infanticide which involved a comparatively slight punishment. As the law

stood at present a woman who desired not to have a child born alive and continuing to exist could go to a professional abortionist—and there were many of them—and tell him that she was expecting her delivery at such a time and that before it had got a separate existence he was to kill it. It was the law of England that if this were done he would commit no offence whatever, and if the amendment were carried that monstrous condition of things would still be the law of England. Mr. Justice Talbot had assured him that there were far more of these cases than people who did not attend assizes had the least idea of. The proposal of the Bill was not suddenly forced upon an astonished world; it had been thought of for a long time. They were not creating a new offence, except in a very technical meaning of the word "offence." He could not accept the amendment, because it would be fatal to the Bill, and would practically give a charter to criminal persons to go on killing creatures who were almost living souls.

A Gap in Criminal Law.

The LORD CHANCELLOR said that in speaking on this Bill, which was a non-party measure, he was expressing his own and not the Government's views, charged perhaps with special responsibility having regard to his official position in the House. The Bill having been given a second reading, the House had committed itself to the principle that there was a gap in the criminal law which it was desirable to fill. They must consider what was the right way to stop that gap and determine exactly what the gap was. It was by law murder deliberately to take the life of a child when it had once become a separate entity and had in a legal sense a separate existence. It was a felony to kill a fœtus. But by English law a child had not got a separate existence merely by reason of the fact that it was born; it had to be proved that the child had acquired a separate existence and that circulation was separate and distinct from that of the mother. They must appreciate that attention had not been drawn to the fact that this was a way to procure what was practically abortion with impunity, and they were aware that unfortunately there were people who made a trade of procuring abortion, and a profitable trade in proportion to its danger. During the second reading debate on the Bill he had expressed regret that public attention had been drawn to what had not been generally known, and he feared that with the public knowledge now given advantage might be taken of this gap in our jurisprudence. Now that the gap had been disclosed it became incumbent on them to close it. The practice of abortion was rife in this country. If the amendment was carried an abortionist would be able to say to a woman, "I cannot take the risk of procuring an abortion, but tell me whenever your child is being born, and I can get rid of it with perfect safety and I shall have committed no offence at all." As to Lord Atkin's point about the difficulty which would be created for a doctor who was acting in good faith, he (the Lord Chancellor) advised Lord Darling to accept or introduce an amendment which would make it clear that the doctor was not charged with the burden of proving that he was acting in good faith; or, if their Lordships preferred it, to accept the suggestion of Lord Merrivale that no prosecution should take place under the Bill without the previous fiat of the Attorney-General. From experience he thought probably that would be a very adequate protection. He did not think that when they had made it clear that as long as the act was done in good faith it was no criminal offence that they were really putting the medical man in a position of embarrassment, because one knew that it was necessary sometimes to procure abortion for the sake of the mother of the unborn child, and he had never heard that any doctor had been embarrassed, or had hesitated in the discharge of that duty, by reason of the knowledge that if he was not acting in good faith he would be guilty of a criminal offence. At the same time he agreed that care must be taken to see that the offence was not made to go farther than was necessary. He submitted that the amendment ought to be rejected and that the Bill ought to be allowed to remain in its present form, but that, probably most conveniently on the Report stage, some provision might properly be inserted to secure that the position of the doctor, or the properly certified nurse, or midwife, or nurse acting as a legitimate *accoucheur*, should be adequately protected.

Lord ATKIN, in pressing his amendment to a division, repeated his view that if their Lordships passed the Bill in its present form there would not be sufficient protection for medical men and registered midwives. The Bill went much too far and involved possible hardship to professional men and women.

The amendment was defeated by 10 votes to 11.

Clause 1 and the remaining clauses of the Bill were agreed to and the Bill was reported without amendment to the House.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 5TH.

Health of the Mercantile Marine.

Dr. VERNON DAVIES asked the President of the Board of Trade if he had consulted the Minister of Health with regard to the preparation of an annual report on the health of the merchant service; and, if so, what decision had been arrived at.—Mr. H. G. WILLIAMS, Parliamentary Secretary to the Board of Trade, replied: As a result of consultations which have taken place between the Ministry of Health and the Board of Trade, a joint standing committee has been set up to advise the two departments on matters of common interest affecting the health of the Mercantile Marine. The question of the preparation of a report on the health of the Mercantile Marine will be one of the first questions which the committee will be asked to consider.

THURSDAY, Dec. 6th.

Women Patients in Mental Hospitals.

Sir ROBERT NEWMAN asked the Minister of Health how many women patients of unsound mind were detained in borough or county mental hospitals in England and Wales where there was no woman member on the visiting committee; how many of these were detained in hospitals under the control of councils who had no women members and were prevented by law from co-opting women on these committees; and whether he intended to propose legislation making it compulsory that a certain number of women should be appointed to serve on all county and borough mental hospital visiting committees where women were detained.—Mr. CHAMBERLAIN replied: Information in regard to the first part of the question is not available. The point raised by my hon. friend in the latter part of the question has been noted for consideration when legislation dealing with the subject is proposed.

Factory Inspection in Glasgow.

Mr. BUCHANAN asked the Home Secretary the number of factories employing women in the city of Glasgow last year which were inspected by factory inspectors; the number not so inspected; and how many prosecutions took place as the result of visits paid.—Sir WILLIAM JOYNSON-HICKS replied: I am informed that the figures are 1259 factories inspected during 1927, 191 not inspected, and 13 prosecutions resulting from the inspections.

Disinfection of Taxi-cabs.

Mr. DAY asked the Home Secretary whether his attention had been called to the evidence given in a recent case in which it was stated that taximeter cabs in garages were used for sleeping in at night by homeless persons; and whether there were any regulations making it incumbent upon the proprietors of all taximeter cabs to have them regularly disinfected.—Sir W. JOYNSON-HICKS replied: Inquiry has been made at the garages of motor-cab proprietors and it has been ascertained that the use of taxicabs for sleeping in at night or for any unauthorised purpose is not countenanced by the proprietors of these vehicles. If it is done, it is done without their knowledge or consent. The disinfection of taxicabs is not a requirement in the Commissioner's Conditions of Fitness, but it is required by law when the vehicle is known to have conveyed a person suffering with an infectious disease. It is the general practice for proprietors to brush and dust the interiors of the cabs before they are taken from the garages to ply for hire, and in many cases it is known that the linings and cushions are sprayed with some form of disinfectant and the floors scrubbed with soft soap and hot water. Motor-cabs are continually under the surveillance of public carriage officers and numerous cases are reported to them annually where it is considered that the interiors of cabs are unsuitable in the public interest from the point of view of cleanliness.

MONDAY, DEC. 10TH.

The Distressed Areas.

Mr. DAVID GRENFELL asked the Prime Minister whether he would take steps to co-ordinate under Government auspices the various agencies which were taking part in relieving distress and hardship in the depressed industrial areas, and whether the Government would give a grant towards a fund for this purpose.—Mr. BALDWIN replied: The whole matter is under the close consideration of the Government, and a full statement will be made at an early date. I can, however, make the following statement for the relief of distress in the coalfields, it has become necessary to set up some machinery for their co-ordination. At the same time the Lord Mayor has invited the Government to place at his disposal the staff and office accommodation

necessary to deal with the additional work due to the recent expansion in the operations of his fund. The Government have gladly responded to this request, and Mr. Noel Curtis-Bennett, C.V.O., has been appointed as organising secretary of the fund. In addition to his duties in connexion with the Lord Mayor's Fund, Mr. Curtis-Bennett will also undertake the organisation of a general clearing-house of information for the purpose of co-ordinating the numerous efforts which are now being made to relieve distress in the coalfields. In this work of co-ordination the Government feel sure that they can rely on the cordial co-operation of all the various relief agencies.

Meals for School-children

Mr. JAMES HUDSON asked the President of the Board of Education (1) how many local education authorities in South Wales and Durham were carrying out in the schools the process known as medicinal feeding; of what diet did this process consist; and whether he was exerting any influence upon the authorities to adopt this process in preference to the provision of meals as allowed under the Education (Provision of Meals) Act. (2) How many local authorities in the mining districts of South Wales and Durham had adopted the Education (Provision of Meals) Act and were providing meals on the ground that children were hungry; how many authorities had not done so; and whether he had influenced the policy of the education authorities in this matter. (3) If he had made recommendations to the local education authorities as to the frequency of medical examination of all children in the schools of the distressed areas; and what length of time, computed on an average of all these children, elapsed between one examination and the next when these were undertaken for the discovery of such malnutrition as the Board considered requisite for the provision of school meals.—Lord E. PERCY replied: Of 20 local authorities in the mining districts of South Wales and Durham 12 are already providing meals for school-children, two are preparing to do so, and six are not, so far as I know, providing any meals. Five of the authorities who are now providing meals are doing so on a medical basis of selection, and I understand that one other authority is preparing to adopt this basis. Some months ago I communicated with the local government authorities in other mining areas suggesting that a special medical survey of the schools should be made before the end of the summer term. As a result of this survey feeding has now been undertaken in certain of these areas also. Children selected on a medical basis may be provided with ordinary dinners, or with special nourishment, such as milk, cod-liver oil, and malt. I have emphasised the importance of local authorities making adequate provision for malnourished children on many occasions during the course of this last year, and I have pointed out some of the advantages of the medical basis of selection as compared with the income basis, but I have put no pressure upon them to adopt the former in preference to the latter. Where the medical basis is adopted I have urged that borderline cases should be re-examined at frequent intervals, and that the schools as a whole should be periodically re-surveyed. In certain cases arrangements are also made for the temporary feeding of children between the visits of the medical officers if the head teacher has reason to believe that any child is not receiving sufficient food. Perhaps I may add that the distinction which appears to be drawn in the hon. Member's questions between medicinal feeding and feeding children who are hungry is based on a misapprehension. "Malnutrition" for this purpose means that the child is "unable by reason of lack of food to take full advantage of the education provided for it." This is the test prescribed by the Education Act, and the distinction is between selection on this basis by medical inspection and supervision of the children themselves and selection according to the size of the parents' income.

Mr. JENKINS asked the President of the Board of Education: (1) What number of Glamorgan children in the elementary schools were receiving milk and malt; whether these children were improving in health and physique; were they receiving the nourishment for seven days weekly or for school days only; and what percentage of the cost would be borne by the Board. (2) What percentage of attending school were in need of food; and, if there were any, would he make a grant for that purpose.—Lord E. PERCY replied: In the schools which have been surveyed by the Glamorganshire Education Authority the percentage of malnourished children was found to vary between 0.9 and 8.9. The number of school-children receiving milk during the week ending Nov. 30th was 698, of whom 57 were given, in addition, cod-liver oil and malt. I am advised that the improvement in health and physique shown by children who have received this treatment for some time is clearly marked. I understand it is provided on school days only. Grant is payable by the Board on the Authority's net expenditure at the rate of 50 per cent.

Anti-distemper Vaccine.

Mr. CRAWFORD asked the Minister of Agriculture if he was in a position to state whether the recently discovered anti-distemper vaccine was an effective preventive of that disease; and, if so, whether the Government was prepared to give aid in making its application universal.—Mr. GUINNESS replied: I am aware that the Field Distemper Research Committee has recently announced that an effective method of vaccinating dogs against distemper has been discovered. I understand that the Committee has offered to assist commercial laboratories or institutions willing to prepare the vaccine and make it available to the public. No public funds are available to assist the preparation or distribution of the vaccine. The Ministry's responsibility in respect of diseases of the dog is confined to diseases such as rabies, which are communicable to farm live-stock or human beings.

Mr. CRAWFORD asked whether, if this was an effective preventive, it did not mark a very important milestone in the treatment of dogs, and if the Government could help in the efforts which were being made in this direction by recommending a grant to help to make the application of the vaccine universal.—Mr. GUINNESS replied that he agreed as to the great importance of this discovery, but he did not see any necessity for a Government grant, seeing that the discovery was now past the experimental stage, and there was every hope that it would be taken up in the ordinary course by those whose business it was to supply these vaccines.

Dr. VERNON DAVIES: Is it not a fact that this is a direct result of experiments made on dogs?—Mr. GUINNESS: I believe that is so.

TUESDAY, DEC. 11TH.

Treatment of Blind Persons in Scotland.

Mr. BUCHANAN asked the Secretary of State for Scotland if he had received any request from the West of Scotland Committee for the Welfare of the Blind for permission to spend added sums for the treatment of the blind; if he could state the nature of such request; and what had been the answer.—Sir JOHN GILMOUR replied: I assume that the hon. Member's question has reference to recent proposals by the Glasgow and South-West of Scotland Joint Committee for the administration of the Blind Persons Act to establish a central clinic for the medical certifications of blind persons and to institute a scheme of allowances to blind persons who are unemployable. The Scottish Board of Health have approved the proposal to establish a central clinic. They have also indicated to the Joint Committee that they will be prepared to approve any schemes of allowances on reasonable lines that the Joint Committee may submit, but that no State grant will be available towards the cost of such a scheme.

Mr. BUCHANAN asked if it was not possible for the Secretary for Scotland to reconsider the question of a State grant for this very laudable service.

Sir J. GILMOUR said that the whole matter would come under review in the reform of local government with which the House was now dealing.

Mr. N. MACLEAN asked whether, as the Secretary for Scotland was so determined to approve of this particular object, that approval ought to carry with it some form of State grant.

Sir J. GILMOUR: Not necessarily.

Share Fishermen and National Health Insurance.

Sir ROBERT HAMILTON asked the Secretary of State for Scotland if he was able to state when the regulations covering the payment of contributions in respect of the admission of share fishermen to national health insurance would be published.—Sir JOHN GILMOUR replied: Notice of proposal to make a special Order will be published in the *Gazette* on Friday next, and a provisional special Order will be laid before the House immediately thereafter.

Relief of Distress in Yorkshire.

Mr. RENNIE SMITH asked the President of the Board of Education if he could give a detailed statement of the needs of school-children in the West Riding of Yorkshire as to food, boots and shoes, and clothing, and the extent to which these needs were being met by the activities of his department.—Lord EUSTACE PERCY replied: There are 22 education authorities in the West Riding. Of these, during the week ended Dec. 1st, 12 were providing meals for 5000 children. I have, as yet, received no official return from the West Riding County Authority, but I understand that they also are now feeding about 1000 children. Of the remaining nine authorities, some are understood to be making preparations for feeding. Surveys by the authorities' medical officers of the condition of the children were conducted in a number of the areas last summer, and recently

in the Barnsley area. The results of the surveys varied considerably in different areas—e.g., 8 per cent. of the children were found to be malnourished in the districts of the county surveyed, and 3.6 per cent. in Barnsley. In Doncaster, Pontefract, Rotherham, and Sheffield the surveys failed to reveal at that time any abnormal conditions. The surveys are concerned primarily with the state of nutrition of the children, and I have not the same amount of information in regard to boots and clothing, but they tended to confirm what is generally known as to the unsatisfactory state of the children's boots and clothing in the distressed areas. Thus, in the West Riding survey of last summer 21 per cent. of the 44,000 children examined were found to have bad boots; in the recent Barnsley survey approximately 6 per cent. were returned as badly clothed.

Obituary.

SIR JOHN PHILLIPS, M.D. CAMB., F.R.C.P. LOND., J.P.

WE regret to announce the death of Sir John Phillips, honorary physician to the Queen, which occurred in London on Saturday last at the age of 73 years.

John Phillips was born at Pavenham, near Bedford, on July 6th, 1855, his father being Zachariah Phillips, of Birchmoor Manor, and his mother Ann Ayres, of Barford. He was sent to school at Bedford, from which he entered St. John's College, Cambridge, where he took the Natural Science Tripos before going on to clinical study at King's College Hospital, London. After qualifying M.R.C.S. Eng. in 1879 and M.B. Camb. in 1881, his bent soon showed itself in the direction of obstetrics, and he worked steadily up the ladder at King's College Hospital, where he was elected assistant obstetric physician in 1889 and full physician in 1898. On retiring after 17 years' service, in 1915, he was appointed consulting obstetric physician. During the greater part of this time he was lecturing on obstetric medicine at King's College, where he held the chair of obstetrics from 1904 to 1915; he was also physician to the British Lying-in Hospital and obstetric physician to the Bromley Cottage Hospital. He became a Member of the Royal College of Physicians in 1885, and was elected to the Fellowship in 1892.

At King's College Hospital he succeeded Dr. W. S. Playfair on the staff, and he was associated for many years with this renowned accoucheur both in hospital work and in private practice. Like most of his generation of specialists, Phillips was more of an obstetric physician than a gynaecological surgeon. He had remarkable hands, which might have been specially designed by Nature for his work; the fingers were unusually long, fine, and flexible. To those who had the good fortune to see him at work his gentle

SIR JOHN PHILLIPS.

Photograph by Elliott & Fry.

manipulative skill seemed almost uncanny. He seemed never to force and never to injure. With such attainments added to a natural charm and gravity of manner, and an impressive appearance, he quickly secured the best private midwifery practice in London, and held it for as long as he wanted. His experience and eminence early brought him to the notice of the Royal Family, and he was appointed honorary physician to the Queen in 1918. The surgery of gynaecology he had to teach himself—he inherited no tradition, and none of his immediate seniors at his hospitals had a surgical bent—and it was remarkable what a high degree of skill he reached. His diagnosis was most careful, and very few of his patients were operated on until they had spent at least a week in his ward under observation, including an examination under an anæsthetic, and every method of investigation which was deemed helpful. In consequence he scarcely ever met anything unexpected when he opened the abdomen. He was a deliberate, careful operator, who paid great attention to hæmostasis, and employed antiseptics liberally. Needless to add, his operative results were extremely good.

Phillips was far too busily engaged in the practice of midwifery to be a prolific writer during the last half of his professional career, but in his earlier years he contributed freely to the literature of his specialty. The "Outlines of Diseases of Women," which first saw the light in 1893, was designed for the use of the student and junior practitioner, and kept closely to first principles, stress being laid on the importance of accurate acquaintance with the anatomy of the female pelvic organs for the proper study of the diseases of women. This text-book ran through four editions between its first date of publication and 1906. He was particularly interested in everything that might lead to the amelioration of the pains of childbirth, and his contributions to medical journals include papers on the value of cocaine in obstetrics, and on the analgesic value of antipyrin administered intra- and post-partum. He contributed a chapter on plastic operations in gynaecology to the second edition of Allbutt and Playfair's System of Gynaecology, and on vaginal operations to Cheyne and Burghard's System. Ten years ago in our own columns he considered the lessons to be drawn from the seven maternal deaths which had taken place among some 2100 confinements which he had conducted in private over a period of 35 years. From 1893 to 1895 he was one of the co-editors of the King's College Hospital Reports.

Sir John Phillips married in 1890 Rachel Rattray, daughter of the late Robert Tweedie Middleton, M.P., D.L., by whom he had one son and three daughters. Her death in 1915 ended an ideally happy union. To this misfortune was added another—namely, a gradual failure of vision due to glaucoma, which was not arrested by the operation of iridectomy. For the last five years of his life he was almost completely blind, and during this time he was devotedly cared for by Miss Beatrice Margaret Naish, daughter of the vicar of Upnor, Kent, whom he married in 1926.

NORTHAMPTONSHIRE HOSPITALS.—On Saturday last Princess Mary opened an extension of the Manfield Orthopaedic Hospital and laid the foundation-stone of two new operating theatres at Northampton General Hospital.

PAYMENT TO HOSPITAL IN ACCIDENT CASES.—At Leeds Assizes on Dec. 1st damages of £899 were awarded to a bricklayer who brought an action against a co-operative society for alleged negligent driving, whereby he was injured. The jury found for the plaintiff. In entering judgment for the amount claimed, Mr. Justice Roche directed that £160 be paid to the York County Hospital, where the plaintiff had been a patient.—The board of management of the Royal Salop Infirmary has been authorised to enforce claims for maintenance owing to the increasing demands made on the institution for the treatment of accident cases. Charges will be made where patients have private means or are insured, or have a legal claim for damages against the person responsible for the accident.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following degrees were conferred on Dec. 7th:—

M.D.—Wilfred Shaw.

B.Chir.—H. N. Webber (by proxy) and Harold Girling.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Council considered the following resolution, which was carried at the annual meeting of Fellows and Members on Nov. 15th.

That this fortieth annual meeting of Fellows and Members again affirms the desirability of admitting Members, who constitute nine-tenths of the College, to direct representation upon its Council.

Further, that in consideration of the importance of the health of the nation and of the fact that some 18,000 Members are in daily contact with the sick, it is most desirable, for the benefit of the public as well as of the College, that Members fulfilling such an important function should have some share in the deliberations of the College to which they belong.

The following reply to the resolution was adopted:—

In view of the recent postal vote of the Fellows, the Council is not prepared to take into further consideration at the present time the question of altering the constitution of the College so as to give Members of the College direct representation on the Council.

The main function of the College is to promote the study and practice of surgery. If there are any matters in this connexion affecting the health of the nation to which Members of the College wish to draw attention, an opportunity for so doing is afforded at the annual meeting of Fellows and Members, while the Council will at all times welcome and give careful consideration to representations made to it by any Member or body of Members of the College, in reference to matters which come within the functions of the College.

At a meeting of the Council of the College on Dec. 5th, with Sir Berkeley Moynihan, the President, in the chair, Prof. Ernest W. Hey Groves was elected a member of the Court of Examiners in the vacancy occasioned by the retirement in rotation of Mr. V. Warren Low.

At the Final Examination for the Fellowship held from Nov. 15th to 29th, 122 candidates presented themselves, of whom 39 were approved (38 men and 1 woman). Three candidates, although successful at the examination, have not yet complied with the by-laws and are therefore not entitled to receive their diploma. Diplomas of Fellow were accordingly conferred upon the following 36 candidates:—

H. S. Allen, Cambridge and St. Thomas's; C. B. Andrews, Guy's; J. C. Barrett, V.C., St. Thomas's; C. E. Beare, Middlesex; J. M. Buchanan, Melbourne and London; R. W. Butler, Cambridge and St. Thomas's; A. M. Clare, Leeds and London; J. B. Crabtree, St. Bart's; J. Crooks, Edinburgh; J. H. Doggart, Cambridge, St. Thomas's, and St. Bart's; V. H. Ellis, Cambridge and St. George's; G. M. Gray, Aberdeen; Dorothy W. Hall, Liverpool and St. Mary's; A. W. Holgate, Univ. Coll. M. H. Hussein, Cairo and St. Bart's; B. L. Jefferies, St. Bart's; J. S. Loughridge, Belfast and St. Bart's; D. H. MacLeod, Middlesex; A. McMillan, Birmingham; C. M. Marshall, Otago; J. P. Monkhouse, St. Mary's; F. W. G. Nash, Middlesex; E. S. Page and G. E. Parker, Cambridge and St. Thomas's; T. V. Pearce, St. Thomas's; I. Price, King's Coll. and London; L. A. Richardson, Cambridge and St. Thomas's; A. Sourasky, Leeds; H. B. Stoddard, Cambridge and St. Bart's; G. H. Steele, Univ. Coll.; S. N. Taylor, Manchester; C. I. Tucker, Cambridge and St. Thomas's; J. M. Turner, Guy's; G. B. W. Walker, Cambridge and St. Mary's; J. J. Walsh, Dublin and London; and J. R. M. Whigham, St. Mary's.

Diplomas of Member were conferred upon the following:—

A. S. Rajasingham, Ceylon and Middlesex; and Florence Whitrow, Manchester.

Licences in Dental Surgery were conferred upon the following 48 candidates:—

F. Allott, C. A. W. Archer, and L. Ashling, Guy's; D. B. Atkinson, Royal Dental; W. L. Baker, Univ. Coll.; W. J. Brown and G. M. Conder, Royal Dental; H. J. Cracknell and H. M. Crombie, Guy's; H. H. Daniels and T. F. Dixon, Royal Dental; J. G. Donnan, J. G. T. Edmonds, and I. C. Fisher, Guy's; H. W. F. Freeth, Royal Dental; H. S. Gare, Guy's; A. A. Garfat, Univ. Coll.; U. Goldberg, Royal Dental; W. M. Graves-Morris, Guy's; J. Greenhalgh, Manchester; G. E. Hansen, C. S. Henderson, F. L. Rossell, C. N. Howitt, E. C. Irish, and F. R. Kearsley, Guy's; B. Kopkin, Univ. Coll.; S. Kutnowski, London; W. H. Lean, Royal Dental; C. M. Leckie and H. O. Lyne, Guy's; Muriel H. Millard, Royal Dental; W. N. Pike and P. J. Pretty, London; E. S. Rose, Royal Dental; W. J. Denton; A. W. G. Small and J. T. F. Tingle, Guy's; W. Underhill and K. C. B. Webster, Royal Dental; D. S. H. Wood, Univ. Coll.; S. F. Wright, Guy's; and A. Zamkov, Royal Dental.

ROYAL SOCIETY OF MEDICINE.—The Society's house and library will be closed from Saturday, Dec. 22nd, to Thursday, Dec. 27th, both days inclusive.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Nov. 21st the degree of Ph.D. in Immunology was conferred on J. T. Cornelius, of the Lister Institute. Prof. G. E. Gask, director of the Surgical Unit, St. Bartholomew's Hospital, has been elected Dean of the Faculty of Medicine for the period 1928-30.

The Geoffrey E. Duveen Travelling Studentship in Oto-Rhino-Laryngology, of the value of £450, will be awarded annually to a student who has obtained the degrees of M.B. and B.S. in the University. The tenure of the studentship will in the first instance be for one year, which will be spent in study abroad, but such tenure may be extended for one or two years and during the extended period the student may be allowed to undertake research at the Royal Ear Hospital or some other laboratory approved for the purpose. Applications must be made on the prescribed form obtainable from the Academic Registrar of the University, and should be sent so as to reach him not later than Dec. 31st.

UNIVERSITY OF BRISTOL.—A dissertation by A. M. Critchley for the degree of Doctor of Medicine has been approved.

At recent examinations the following candidates were successful:—

C. B. Perry.

M.D.

FINAL EXAMINATION FOR M.B., CH.B.

Part I. (including Forensic Medicine).—*J. F. Coates, Erelinc M. D. M. Collinson, *H. F. G. Corfield, J. L. W. Davies, J. J. Giraldi, R. D. Jones, *G. F. Langley, R. A. Latter, R. P. Lucas, J. E. Newton, and S. C. Wake.

* With distinction.

Part I.—U. M. Hopkins, W. L. Sleight, and H. M. Strover.

Part II.—A. A. Dowling (with distinction in Obstetrics) and H. D. Pyke (with second-class honours and distinction in Obstetrics). G. R. Fells (with distinction in Public Health) and Ethel M. Redman. *In Group II. (completing examination):* Phoebe C. Vine.

Barbara J. Shapland passed the Final Professional Examination for the Diploma in Dental Surgery.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—At the annual meeting of the College on Dec. 6th Dr. Robert A. Fleming was re-elected President for the ensuing year; Dr. Robert Thin was nominated vice-president; and Dr. G. Lovell Gulland, Dr. John Orr, Dr. William Fordyce, Dr. Edwin Bramwell, and Dr. A. Fergus Hewat were elected to form the Council.

HOSPITAL MEMORIAL TO LORD BUCKLAND.—Part of the memorial of the town of Merthyr to the late Lord Buckland is to be an enlargement of the Merthyr General Hospital, which will be called "The Buckland Extension."

ROYAL INSTITUTE OF PUBLIC HEALTH.—The next Congress of the Institute will be held at Zürich during Whitsuntide, 1929, from Wednesday, May 15th, to Monday, the 20th, under the presidency of Lord Meston, Chancellor of the University of Aberdeen. The Congress will be conducted in English in the following sections: (1) State Medicine and Municipal and Social Hygiene; (2) Industrial Hygiene and Industrial Diseases; (3) Child Welfare, School Hygiene, and Women and Public Health; (4) Pathology, Bacteriology, and Biochemistry; (5) Tuberculosis; (6) Climatology and Sports Hygiene; and (7) Veterinary Medicine and Meat Hygiene. Arrangements for travel and hotels are in the hands of Sir Henry Lunn, 5, Endsleigh-gardens, Euston, London, W.C. 1, from whom particulars can be obtained.

NATIONAL UNIVERSITY OF IRELAND.—The Senate last week made certain appointments to the staff of University College, Dublin. To fill the vacancy in the chair of surgery left by the death of Mr. J. S. McArdle, Senator H. L. Barniville was appointed professor of surgery, and Mr. H. S. Meade, professor of regional surgery. In dividing the duties of the chair of surgery into two the Senate has followed the same precedent as in the appointments to the chairs of medicine and midwifery, both of which were vacant in the last few years.

Mr. Barniville was educated at University College, taking his degree in 1911 and proceeding to the M.Ch. Degree in 1916. He has been for many years one of the visiting surgeons to the Mater Misericordiae Hospital, and has been a member of the Senate of the Irish Free State since its establishment in 1922.

Mr. Meade was educated at the Catholic University School of Medicine and obtained the licences of the Royal College of Physicians and Royal College of Surgeons in 1909, proceeding to the Fellowship of the latter body in 1910. During the war he served with the Royal Army Medical Corps and with the French Army Medical Service. He has been one of the visiting surgeons to St. Vincent's Hospital for several years.

At the same meeting of the Senate Dr. A. R. J. Dungan was appointed lecturer in medical jurisprudence in University College, Dublin.

FREEMASONS' HOSPITAL.—The board of management of the Freemasons' Hospital and Nursing Home have bought a site of three and a half acres at Ravenscourt Park, Hammersmith, for the erection of their new buildings.

INSTRUCTION FOR D.P.H.—A three months' course of lectures and demonstrations on Clinical Practice and in Hospital Administration will be given at the North-Eastern Hospital, St. Ann's-road, Tottenham, London, N., by Dr. F. H. Thomson, medical superintendent, on Mondays and Wednesdays, at 4.45 P.M. and alternate Saturdays at 11 A.M., beginning Monday, Jan. 7th, 1929.

ROYAL STATISTICAL SOCIETY.—At a meeting of this society, to be held in the Hall of the Royal Society of Arts, John-street, Adelphi, London, W.C., at 5.15 P.M. on Dec. 18th, Mr. H. E. Soper will read a paper on the Interpretation of Periodicity in Disease-Prevalence.

CHELSEA CLINICAL SOCIETY.—A meeting of this society will be held at the Hotel Rembrandt, Thurloe-place, London, S.W., on Tuesday, Dec. 18th, at 8.30 P.M., when Mr. J. E. R. McDonagh and Prof. Alexander Fleming will open a discussion on Antiseptics. The meeting will be preceded by dinner at 7.30.

SOCIETY FOR THE STUDY OF INEBRIETY.—The next meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, Jan. 8th, 1929, at 4 P.M., when Dr. Catherine Chisholm will open a discussion on Alcohol and Drug Addiction in Relation to Women and Children.

LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner, held on Dec. 6th at the Savoy Hotel, was aptly described by the chairman, Prof. Winifred Cullis, as a family gathering to which certain privileged guests had been invited. The result was a large party, for something like 450 were present, showing that the privilege of an invitation was appreciated. The dinner, served at small round tables, was excellent and not too long, and this applies also to the speeches. The loyal toasts were honoured with especial fervour, since the chairman had called for an expression of sympathy with the Queen in her anxiety. Mr. John Buchan, in wishing prosperity to the school and hospital, said that his realisation of the value to the community of the work of doctors dated from the South African War, when he was in charge of concentration camps under Lord Milner. At this time also the beneficent activities of the committee of women workers, convened by Dame Millicent Fawcett, were in his mind.

...a profound conviction of the value of the work of doctors dated from the South African War, when he was in charge of concentration camps under Lord Milner. At this time also the beneficent activities of the committee of women workers, convened by Dame Millicent Fawcett, were in his mind. In his walk of life in which she was given a quarter of a chance. The story of the school, he said eloquently, was one of courage, hard work, patience, optimism, and good sense, and its development was based on the only true equality—equality of competence. The chairman, in a graceful response, referred to changes in the staff during the past year, to the extensions in the hospital, and to the additional educational facilities provided, of which the most notable was the opportunity afforded for teaching in psychiatry at the Horton Mental Hospital at Epsom under Lieut.-Colonel J. R. Lord. The school had been successful in academic matters and in sport; and the entry of students had increased. In this connexion the chairman deprecated the closing to women of all but one of the other teaching hospitals of the University of London, not only because it was an unmerited slur on women medical students, but also because the fact that the prosperity of the London (R.F.H.) School of Medicine for Women had been maintained and increased in the face of competition had been a matter of legitimate pride. Lord Riddell, in proposing the health of the guests, found for each an apt descriptive phrase. Miss M. D. Brock, headmistress of the Mary Datchelor Girls' School, replied to this toast with a witty comparison between the attitude of the public towards schoolmistresses and towards women scientists. Major Ian Hay Beith, who also replied for the guests, referred, with legitimate sadness, to the monotony with which the public demanded eternally from a writer the kind of work which they had decided he ought to provide for them, and he described Mr. Buchan as the one living author who seemed able to compel the public to read what he chose to write and over a very large range of subjects. The guests included Dr. Andrew Balfour, Miss Lilian Baylis, Sir Walter Fletcher, Miss E. C. Higgins, Mr. Alfred Levy, and the Editors of the *British Medical Journal* and *The Lancet*. Lady Briscoe thanked Prof. Cullis for presiding, and the latter modestly disclaimed praise for the success of the dinner, which, she said, was entirely due to the labours of the honorary secretaries, Dr. Haldin Davis and Miss S. Widdows. In this spirit of great good humour the company adjourned to the dancing hall.

NEEDS OF THE LONDON HOSPITAL.—Presiding at the quarterly Court of Governors last week, Lord Knutsford reported that the quinquennial appeal had so far produced only the disappointing result of £112,000. The hospital, he said, is sorely in need of radium. A new children's department and a new heart department are also required.

AN EDINBURGH SUBSCRIBERS' LEAGUE.—At the annual meeting of the League of Subscribers to Edinburgh Royal Infirmary it was stated that the members now number 120,000, and that the amount raised during the year recently closed was £21,400. The membership includes the miners of Fife and the Lothians.

DONATIONS AND BEQUESTS.—Sir William Berry and Sir Gomer Berry have made a joint gift of £20,000, payable over the next eight years, to the King Edward VII. Hospital, Windsor, in connexion with the special appeal for £55,000 for the rebuilding of the two wards recently destroyed by fire and the erection of a new nurses' hostel.—Mr. Robert Ottley, of Molyneux Park Hotel, Tunbridge Wells, left, among other bequests, £2000 to be divided between the Royal Infirmary, Manchester, and the London Hospital.—Mr. George Edward Skinner, Redland, Bristol, besides other bequests, left £1000 to Müller's Orphanage, Ashley Down, and £200 each to the Bristol Blind Asylum, the Bristol General Hospital, the Bristol Royal Infirmary, the Bristol Royal Hospital for Sick Children and Women, the Bristol Eye Hospital, and the residue of the property between ten charitable institutions.—Mr. William Taylor Hague, of the Hollies, Werneth, Oldham, left £3000 for such institutions or societies having for their object the relief of the sick or of poverty as the executor may think fit, and £1250 to the Oldham Royal Infirmary.

SEMAINE INTERNATIONALE DE LA LUMIERE.—Under this title a congress and exhibition, organised by L'Institut d'Actinologie de Paris, will be held in the Grand Palais, Paris, from July 22nd-27th, 1929, under the presidency of Prof. d'Arsonval. From the 22nd to the 24th there will be an international congress at which the subjects for discussion are: (1) the choice of a unit of measurement for ultra-violet rays used in medicine; (2) the treatment of tuberculous peritonitis by light; (3) the prophylactic value of ultra-violet rays; (4) the treatment of rheumatic conditions by infra-red rays; and (5) other current topics in actinotherapy. From the 22nd to the 27th there will be an international exhibition of apparatus and one dealing with heliotherapy from the earliest times. On the 25th and 26th conferences will be held on the recent progress of actinotherapy, and during the week an elementary course on this subject will be given by the Director of L'Institut d'Actinologie (Dr. Saidman) and his colleagues. Other fixtures include demonstrations and a reception. Further particulars may be had from Dr. W. Kerr Russell, 12, Park-crescent, Portland-place, London, W. 1, secretary of the British section.

THE M.A.B. AND THE LOCAL GOVERNMENT BILL.—At a meeting of the Metropolitan Asylums Board held on Dec. 8th it was decided to send to the Minister of Health an expression of regret that its representations had not succeeded in bringing about any modification of his proposals so far as they affect the Board. The Board adheres to the view it has previously expressed on the subject of the transference of its functions to the London County Council—namely, that its experience had shown that the management of the central public health institutions of London was a work of sufficient importance and extent to justify the existence of a central body endowed with statutory powers on which the bodies dealing with local affairs in London should be adequately represented. Since its inauguration in 1867 the Board has enlisted the services of a large number of men and women who have devoted themselves to the work of providing, maintaining, and extending where necessary the public hospitals required by London for infectious diseases and tuberculosis, mental hospitals, ambulance and transport services, a training ship, and other lesser services. The whole of the debt of nearly £7,000,000 raised to meet capital expenditure on the erection, acquisition, and equipment of hospitals, &c., has been paid off with the exception of £336,000, representing the expenditure on grant-aided services of which the Government is responsible for one-half. The Board now has under its control some 25,000 hospital beds and in times of pressure employs a staff of 10,000 persons. The hardship felt by the Board at the transference of its duties is summed up in the following words: "The Board is to be involved in the changes through no shortcomings of its own. On the contrary, tribute has been paid by the Minister of Health and the London County Council to the efficiency of its organisation. Its duties have been steadily added to in recent years, and only this year Parliament has imposed upon it fresh and important responsibilities in connexion with the Metropolitan Common Poor Fund, and the Minister of Health has expressed his appreciation of the manner in which the Board has carried on this new work."

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
THURSDAY, Dec. 20th.—5 P.M.: DERMATOLOGY. (Cases at 4 P.M.)

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE,
Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Dec. 17th.—2.30 to 5 P.M.: Medical, Surgical, and Gynaecological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M.: Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M.: Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M.: Dental Clinics. 2.30 to 5 P.M.: Medical, Surgical, and Ear, Nose and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M.: Throat, Nose and Ear Clinics. 2.30 to 5 P.M.: Surgical, Medical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Dec. 18th.—5 P.M., Dr. J. A. Drake: Urticaria.

THURSDAY.—5 P.M., Dr. I. Maende: Pathology Demonstration.

Appointments.

CARSON, F. S., M.D. Belf., D.P.H., has been appointed Admiralty Surgeon and Agent at Barrow-in-Furness.

HUNTER, A., B.Sc., M.B., Ch.B. Edin., Gardiner Professor of Physiological Chemistry in the University of Glasgow.

MAGUIRE, T. J. R., M.B., B.Ch. N.U.I., D.P.H., Assistant Medical Officer of Health, Co. Cork.

OVERTON, P. M., M.B., B.Ch. Leeds, Assistant Anaesthetist to Bolton Infirmary.

PARSONS, L. G., M.D., F.R.C.P. Lond., to the new Chair of Infant Hygiene and Diseases of Children in the University of Birmingham.

SCOTLAND, D. C., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for Brighouse, West Riding.

STIRLING, J. A., M.B., B.S. Durh., M.O.H., Medical Officer of Health, Chesterfield.

WEIR, A. L., M.B., B.Ch. Belf., B.A.O., a Medical Referee under the Workmen's Compensation Act (Northern Ireland) for the County and City of Londonderry.

King's College Hospital: CRITCHLEY, M., M.D. Brist., M.R.C.P. Lond., Junior Neurologist and Lecturer in Neurology; BICKERTON, J. M., B.Ch. Camb., F.R.C.S. Eng., Supernumerary Junior Ophthalmic Surgeon and Ophthalmic Tutor; EAST, C. F. T., M.D. Oxf., F.R.C.P. Lond., Medical Tutor; EDWARDS, H. C., M.S. Lond., F.R.C.S. Eng., Surgical Tutor; SAUNDERS, R. M., M.B., Ch.B. Edin., Obstetric Tutor and Registrar; LUCAS, H. A., L.R.C.P. Lond., M.R.C.S., Pathological Tutor; NEWMAN, C. E., M.D. Camb., M.R.C.P. Lond., and SMITH, R. C., M.B., B.Ch. Camb., M.R.C.P. Lond., Medical Registrars; BELL, J. G. Y., M.B., B.S. Lond., and WOOD, H. L. C., M.B., B.S. Lond., Surgical Registrars; and CAWTHORNE, T. E., L.R.C.P. Lond., M.R.C.S., Registrar in the Ear, Nose and Throat Depts.

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital for Genito-Urinary Diseases, 91, Finchley-road, N.W.—Sen. and Jun. H.S.'s. At rate of £200, £150, and £100 respectively.

Birmingham, Ear and Throat Hospital.—Second H.S. At rate of £150.

Birmingham, General Hospital.—Surg. Reg. Also Asst. Reg.—Surg. O. At rate of £150 and £100 respectively.

Boyleborough Hospital.—Hon. Radiologist.

Brighton, Royal Sussex County Hospital.—H.P. £150.

Bristol Royal Infirmary.—Hon. Asst. Surg. Also Hon. Anaesthetist.

Cambridge, Addenbrooke's Hospital.—Res. Anaesthetist. Also H.P. At rate of £180 and £130 respectively.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.

Connaught Hospital, Walthamstow, E.—Hon. Surgeon.

Derby, Derbyshire Royal Infirmary.—Hon. Asst. Ophth. Surgeon.

Derbyshire Education Committee.—Asst. School M.O. £600.

East Ham Hospital, Shrevebury-road, E.—Hon. P.'s and S.'s.

Exeter, Royal Devon and Exeter Hospital.—Sen. H.S. £200.

Freemasons Hospital and Nursing Home, 27, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.

Gowers' Company.—Research Scholarships, £300.

Reg. £100; of Medicine, £800.

Analyst, Maida Vale, W.—Med:

Hospital for Sick Children, Great Ormond-street, W.C.—Surgeon. *Indian Medical Service.*—Recruitment of European Officers. *Inverness, Northern Infirmary.*—Hon. Surgeon for Ear, Throat and Nose.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £100. *Kensington, Fulham, and Chelsea General Hospital, 194, Fimborough-road, Earl's Court, S.W.*—Res. M.O. At rate of £100.

London County Council.—Asst. Tub. M.O. £600. *Hospital, Gt. Ormond-street, W.C.*—Three at £100.

Luton Borough.—Asst. M.O.H., &c. £600.

Manchester Babies Hospital.—Jun. Res. M.O. At rate of £50. *Manchester, Royal Infirmary, Central Branch, Roby-street.*—Jun. H.S. At rate of £100.

Middlesex Hospital, W.—Jun. Res. Asst. Anaesthetist. At rate of £80.

Middlesex Hospital and Medical School, W.—Medical Registrarship. £300.

National Hospital, Queen-square, W.C.—Res. M.O. £200.

Plymouth City Mental Hospital, Blackdon, near Ivybridge.—Jun. Asst. M.O. £300.

Pontypridd Urban District Council.—M.O.H., &c. £800.

Poplar Hospital for Accidents, East India Dock-road, Poplar, E.—Second Res. O. £175.

Queen Mary's Hospital for the East End, E.—Res. M.O. At rate of £200. H.P. and Cas. O. At rate of £150. Also H.P. and H.S. Each at the rate of £120.

Reading, Royal Berkshire Hospital.—H.P., Second H.S. Also Cas. O. Each at rate of £150.

Royal Army Medical Corps.—Twenty-five Commissions.

Royal Free Hospital, Gray's Inn-road, W.C.—Clinical Assistants *Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.*—H.P. At rate of £100.

St. Helens, County Borough.—Deputy M.O.H. £700.

St. Marylebone General Dispensary, 30, Marylebone-lane, Grosvenor-chambers W.—Physician for Infant Consultations. W.—Med. Supt. £400. Also Medical

Surgeon. £1000.

tal for Women.—Three Asst. H.S.'s. Each

at rate of £100.

Sheffield, Royal Infirmary.—Jun. Aural and Ophthalmic H.S. At rate of £80. H.S. Also Asst. Cas. O. Each at rate of £30.

Shrewsbury, Royal Salop Infirmary.—H.P. At rate of £160.

Sutton, Surrey Downs Hospital for Children.—Jun. Asst. M.O. £500.

Talgarth, Breconshire, South Wales Sanatorium.—Two Asst. Res. M.O.'s. Each £250.

Truro, Royal Cornwall Infirmary.—H.S. £170.

University College Hospital, Gower-street, W.C.—Hon. Clin. Asst. in X Ray Dept.

University of London, South Kensington, S.W.—Geoffrey Duveen Travelling Studentship in Oto-Rhino-Laryngology. £450.

West African Medical Staff.—Vacancies for Pathologists in Nigeria and Sierra Leone. £800.

Wilkesden General Hospital, Harlesden-road, N.W.—Res. H.S. At rate of £100.

Winchester, Hampshire County Council.—Asst. County M.O. £600.

Winchester, Royal Hampshire County Hospital.—Asst. Hon. Surgeon.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at *St. Albans (Herts.)*, *Chelmsford (Essex)*, *Crosby (Lancs.)*, *Shire*, *Mossley (Lancs.)*, *Kilbride (Derbyshire)*, and *Hoylelake (Cheshire)*.

Births, Marriages, and Deaths.

BIRTHS.

HAYDON.—On Dec. 5th, at Kingsdown, Bidford, N. Devon, the wife of L. R. Haydon, L.D.S. Eng., of a daughter.
MARSH.—On Dec. 3rd, at Wellington-road, Edgbaston, the wife of Frank Douglas Marsh, F.R.C.S., of a son.

MARRIAGES.

DAHNE—RANDALL.—On Dec. 3rd, at the Parish Church, Wimbledon, Dr. S. F. Logan Dahne to Mary Katharine, only daughter of Dr. and Mrs. Martin Randall, of Wimbledon.

LINDSAY—MARTIN.—On Dec. 6th, at the West London Synagogue, Sidney S. Lindsay, M.B., B.S. Lond., M.R.C.S., L.R.C.P., of 443, New Cross-road, to Ruth, only daughter of the late Robert J. Martin and Mrs. Martin, of 228, Haverstock-hill, N.W.3.

MORGAN—SMITH.—On Dec. 5th, at the Wesleyan Methodist Church, Crossgates, Leeds, George Morgan, F.R.C.S., to Ann, daughter of the late George Smith, of Cadney, Briggs, Lines.

DEATHS.

BAKER.—On Dec. 2nd, at Devonport, after a brief illness, Thomas Baker, O.B.E., M.R.C.S., L.S.A., aged 76.

HALLIDAY.—On Nov. 21st, at his home, "Derry," Jamaica, B.W.I., Dr. Edward Vivian Halliday, aged 60.

PHILLIPS.—On Dec. 8th, at Queen's-road, N.W., Sir John Phillips, Kt., M.D., F.R.C.P., Honorary Physician to H.M. the Queen.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

NORTH KENSINGTON WOMEN'S WELFARE CENTRE.

THIS centre exists to give medical advice on birth control to those unable to afford the fees of a private medical practitioner. The advice is given by qualified medical women assisted by midwives. During the year ending July 31st, 1928, 1183 visits were paid to the clinic. Of these 351 were new patients, of whom 79 were sent by private doctors and welfare centres for medical reasons; 173 came on the recommendation of other patients. It is the policy of the clinic to discourage childless married women from making use of contraceptives unless they have good reasons for not wanting children, and, moreover, it is the custom to suggest the advisability of a second child. The fact that a perfectly safe and simple contraceptive has yet to be found and that too little is known of the effects of contraception are recognised at this clinic. The committee work in close coöperation with the Birth Control Investigation Committee, of which Sir Humphry Rolleston is chairman. It is hoped to secure over a long period of time some reliable data as to the prevalence, effectiveness, and after-effects of the use of contraceptives both as a whole and also in relation to the various methods employed.

In the copy of the fourth annual report of this centre which has reached us a medical supplement is inserted, wherein an attempt is made to answer the questions commonly asked by members of the profession visiting the clinic. The principle underlying the practice at this centre is to give the advice suited to the physical condition of each patient. A careful history is taken, and the patient examined both bimanually and with a speculum, in order that the most suitable contraceptive method for her may be ascertained. Some occlusive appliance as well as a spermicide is always advised.

Occlusive Appliances.

The occlusive appliance most frequently recommended is some form of rubber cap to be worn by the woman. Three types are in use at the clinic:—

1. *The Dutch cap*, made in 12 sizes, is the one most frequently used. There are two classes of case in which it is unsuitable: (a) where the vaginal outlet has been so torn by childbirth that there is no sphincter action left; in these cases the cap will not stay in position; (b) cases of pronounced uterine prolapse.

2. *The Pro-Race cap* (three sizes) is designed to fit round the cervix itself. It is not suitable (1) in all pathological conditions of the cervical os; (2) when the intravaginal cervix is so short that there is not room for the cap to fit on; (3) for a patient with such short fingers, or such a long vagina, that she is unable to reach her cervix with her fingers.

3. *The Dumas cap* (three sizes) is useful for cases in which neither of the other two can be used. It fits up against the vault of the vagina, covering the cervix, and is unsuitable if (1) the cervix is long; (2) the tissues of the cervix are unhealthy.

Spermaticides.

The spermaticides employed are quinine, lactic acid, and vinegar.

Quinine in the form of the hypodermic tablet of quinine and urea hydrochloride (grs. 2) Parke Davis, is most often advised. This tablet is inserted above the cap, so that the cap holds it in position against the cervix. The cap and tablet are inserted when convenient and can be left in situ for 12 hours. No douching is necessary in this routine.

Lactic acid, made up into an ointment (3 per cent.) is advised, in conjunction with douching, in cases of excessive leucorrhœa. The routine in these cases consists in: (a) smearing the cap with ointment before inserting it, and (b) douching with 1 pint of warm soapy water before and after removing the cap. In no case should the cap be retained in the vagina for longer than 12 hours. Many women who live in overcrowded houses find it difficult to get the privacy and the opportunity to douche, and for this reason this technique is never advised unless there is, for other reasons, a need for douching.

In a certain number of cases (approximately 25 per cent.) both the quinine tablet and the lactic acid ointment are prescribed for use with the cap. These are cases where there is a certain amount of loss of tone in the vaginal walls and outlet, so that, although the cap does not slip out, it may alter its position slightly. Finally, in a small number of cases where it is impossible or inadvisable to fit the patient with a cap, a sheath is advocated for the husband's use, and a soluble pessary of quinine or lactic acid for the wife. Douching is optional in these cases. A cotton-wool tampon soaked in vinegar and water (half and half) and smeared all over with vaseline or any grease, is recommended

for those patients who cannot learn to adjust the cap correctly.

It is not claimed that these methods are perfect, but they can only be improved as knowledge increases.

Instructions to Patients.

After the patient has been fitted with a suitable cap, she is taught by the clinic nurse how to insert it within the vagina so that it covers the cervix. Great stress is laid upon the necessity of feeling the cervix through the cap, since if the cap is pushed into the anterior fornix the cervix is left exposed. The patient pays a second visit at the end of a week, when she is examined with the cap placed in position by herself. Further instruction is given if it is not adjusted correctly.

The examination made at the first visit is repeated at each subsequent six-monthly visit, and detailed notes are made. In this way any pathological condition requiring treatment can be detected, and the effect on the cervix of the use of rubber caps and spermaticides ascertained. It is the experience at this clinic that, with one possible exception, no ill-effects result from such use. Many patients speak of improved mental and physical health owing to the removal of the fear of pregnancy.

The patients advised to attend hospital for treatment include cases of the following: rectocele, cystocele (or both), erosion of cervix, retroversion of uterus, fibromyomata, and ovarian cyst. Private practitioners and official welfare centres are sending increasing numbers of patients. Among these are cases in which instruction in birth control is required on medical grounds, the Ministry of Health having approved that such cases should be referred to the clinic from the welfare centres.

It is of interest to note that the majority (over 80 per cent.) of patients attending the clinic during the last year have already practised some form of birth control—usually coitus interruptus. Satisfaction is expressed that these patients are now able to abandon a practice to which medical opinion is definitely opposed.

ENCEPHALITIS LETHARGICA IN IRELAND.

THE Department of Local Government and Public Health has issued a circular letter to all sanitary authorities in the Irish Free State, drawing their attention to the presence of encephalitis lethargica in several districts in Ireland, and suggesting that the disease should be added to the schedule of notifiable diseases. It is also suggested that cerebro-spinal meningitis and acute poliomyelitis should be added to the schedule in districts where this has not already been done. The circular states that "encephalitis lethargica or epidemic encephalitis is characterised by certain manifestations originating in the central nervous system. As in other general infectious diseases, the symptoms vary considerably in character and severity. In the abortive, mild, or transient type the symptoms are restricted to soreness of the throat, naso-pharyngeal catarrh, headache, vomiting, or diarrhoea, accompanied by slight pyrexia. In the severer forms of the disease, among those who survive the acute attack, many are later afflicted by motor disorders, characterised by rigidity and tremor, or by spasmodic movements and certain forms of paralysis and often by progressive lethargy and stupor. Various degrees of stupor have been noted. In the severest form of attack the patient is described as lying in bed like a log or resembling a waxen image in the lack of expression and of mobility. The prominent symptoms in a material proportion of recent cases have been lethargy and ocular paralysis, myoclonic movements, and sometimes twitching of the abdominal muscles. The disease attacks all ages with a preference for the early and middle periods of life and both sexes nearly equally. The disease appears to belong to that group of maladies (including also cerebro-spinal meningitis and acute poliomyelitis) in which the pathological agent is much more frequently present in the human organism than the clinical symptoms indicate. Although it is difficult to trace the infection from one person to another, it must be assumed that 'mixed cases' and 'carriers' play a large part in the dissemination of these diseases."

THE HUMAN FLEA AND PLAGUE.

At the end of July a mysterious disease was reported from the newly opened-up regions of Manchuria.¹ It raged among the Mongols, causing fever, vertigo, headache, occasionally diarrhoea, and often sudden death, and was not identified until a member of the Manchurian Plague Prevention Service arrived in the first week of September. He found plague bacilli in an inguinal bubo, and Dr. Wu Lien-Teh (known to many people in this country as W. L. Tuck) was sent up by the Marshal at Mukden. He found a curious state of affairs. Although medical practitioners were plentiful they had only the vaguest ideas of plague campaigns, and wasted much time and money in disinfecting rooms and clothing with carbolic acid while the sick and dying lay alone in the devastated villages where frightened police and coolies refused to go. The outbreak picked out a little village of 1800 inhabitants, and the history strongly suggests that it was brought there by a Mongol visitor who died in the local inn. One-fifth of the population of the village died and hundreds of inhabitants fled: fortunately Dr. Lien-Teh was able to check the widespread epidemic that the fugitives might have caused. He was fortunate in the enlightened co-operation of the Marshal and Civil Governor, who gave him the utmost support, both in money and in authority. His trained staff from Harbin set up a bacteriological laboratory in a goods office and plague vaccine was extensively used. About 8 per cent. of patients recovered. An interesting outcome of this campaign is the very strong impression conveyed to Dr. Lien-Teh from the clinical and laboratory work that *Pulex irritans* may—at any rate in Manchuria—convey the bacillus direct from patient to patient without the intervention of the rat.

SMALL-POX IN TIBET.

A TRAVELLER in Tibet has lately written some interesting notes² on the science of epidemiology as practised by its inhabitants. Small-pox infects large areas and is often extremely virulent, and its patients submit willingly to isolation and often notify themselves. The first treatment consists in the performance by the lama of the appropriate ceremonies, and if these fail the patient swallows suitably inscribed papers with the correct invocations. Should no good result follow, the lama applies exorcism, and if the patient dies he is buried, in contrast to the usual custom of cremation or exposure in the desert. Presumably, fuel being scarce, burial is performed to avoid infection. The custom of burning the dead man's skin rug, which Dr. Filchner once saw carried out, is another indication that the idea of infection is not unknown in those parts. An interesting observation he makes is that influenza and catarrh are practically unknown; they only appear when some white man opens a bale of cotton goods from Europe and releases the imprisoned bacteria.

THE "EVERYWAY" ELECTRIC LAMP.

An electric lamp that can be put in any and every position, and will stay where it is put, should be a real boon in the consulting or operating room. Our illustration shows such a lamp. Each part of the apparatus will describe a complete

circle round the points marked A, B, C, D, E, and F, the counter weights holding the limbs in place at the required angle. There are no screws to undo or tighten: a touch of the hand is all that is necessary. The extension radius of the apparatus is 2 ft. 6 in. and the lamp will throw a light on any object within a circumference of 15 ft. The form illustrated can be stood on a table, a bench, or on the floor, and by means of the hollowed out base it can be hung on a nail or hook on the wall. Other patterns can be obtained for use as a reading lamp or as a standard lamp, the latter form being especially suitable for operations. The extension levers of the apparatus are nickel-plated, and the base is of wood laquered with a non-inflammable acid- and alcohol-resisting varnish. The lamp can be obtained from Messrs. Hawksley and Sons, Ltd., 83, Wigmore-street, London, W.1, and from other scientific instrument makers.

HUMAN FITNESS FOR INDUSTRY.

Two small volumes have just been issued, the titles of which might easily have been interchanged. One is by a physiologist,¹ the other by a psychologist,² and each reviews from a different angle the facts disclosed in recent years, mainly through the activities and publications of the Industrial Fatigue Research Board. The one shows *how* the human organism reacts to the milieu of modern industry; the other describes *why* it so reacts. Life to-day, in comparison with 200 years ago, is happier and healthier, because, by lightening human toil through the use of power-driven machinery, we are ever more and more shaping our environment to suit our requirements. But the way in which the means to this end, the new mills of industry and the old human factor, are acting and reacting each on the other is a fascinating study. It is the study of industrial fatigue, which has now passed through an experimental period during which it was far more talked about than understood, and has settled to the stage of painstaking observation and experiment—a stage wearisome to the public but entrancing to the worker. Now and again a report of solid worth, though not easy to read, discloses some new fact or facts. But the additions to the edifice which is being built out of our knowledge concerning human capacity are apt to escape notice. Prof. E. P. Cathcart embodies in his small book lectures given to engineering students—potential works' managers. Herein is clearly explained the practical bearing upon workshop practice of the new knowledge. The physiology of activity is described and of fatigue and monotony. The possibilities of alleviating fatigue, by suiting hours of labour to the requisite physical effort, by fitting the worker to his work, and by the adoption of more convenient methods are explored. The way in which the environment affects working capacity through the influence of ventilation, heating, humidity, lighting, noise, sitting accommodation, and design of machinery is clearly set out. Prof. Pear has been less successful. He seems possessed with the idea that modern industry is some demon specially devised for mangling the mind of man. He shows little appreciation of the advances of recent years and of occupational life as it was lived in pre-machine days. M. C. Buer, in a survey of Health, Wealth, and Population in the Early Part of the Industrial Revolution, has described it as life in overcrowded and soul-destroying hovels, where monotony, if it only meant freedom from the irritation of sickness, was a glorious relief from that bodily pain and ill-health which ended the life of the manual worker at 45. Prof. Pear does not supply practical wisdom which may be put to everyday use, but looks for motives behind action. A chapter dealing with the psychology of laziness makes good reading; it tells clearly how we may react mentally to disagreeable chores, but hardly give sufficient weight to the possibility that Willie's weariness may depend upon endocrine deficiency. This work does not lead us much further.

MEDICAL EDUCATION.

THE Rockefeller Foundation continues to issue its useful and interesting accounts of the equipments and methods in use in teaching medicine and the medical sciences in various parts of the world. The tenth series³ contains 33 well-illustrated articles covering a range from Singapore to Chile; three of them are on medical libraries and how to use them. Every teacher who has done it knows the advantage of going about and seeing other institutions than his own and other methods of instruction, and if he cannot go in person to the institute of physiology and general pathology at Debreczen or the institute for nutrition at Tokyo, he will get some useful hints on what to do and what not to do by reading about them. The schools of pathology, bacteriology, and physiology in the University of Leeds and the courses of instruction given in them are described in this volume by Prof. M. J. Stewart and Prof. B. A. McSwiney, and there is a useful account of the demonstration of biological experiments by optical projection methods by Dr. M. S. Biskind, of the Western Reserve University.

M.D. writes: I have the misfortune to suffer from a chronic osteitis of the lumbar vertebrae and right os iliopectineum, entailing much pain, which especially in later months has yielded in wonderful manner to the exhibition of aspirin. I should be much obliged if any of my colleagues would give me their views as to deleterious effects likely to follow on taking about grs. 30 daily. I have taken that amount for about one and a half years, so far as I can tell without harm.

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(Continued from p. 1222.)

THE following is the text of the official bulletins which have been issued during the King's illness: Sir Stanley Hewett and Lord Dawson.

THURSDAY, DEC. 6TH. 10.45 A.M.

The King has passed a fair night and the temperature this morning is lower. The general condition is slowly improving and the infective process which remains severe, is becoming more localised.

8.20 P.M. The King's general condition remains the same as that reported in this morning's bulletin. The localisation of the infection at the base of the right side of the chest is rather more defined, it conforms to the progress of the illness during the two days. (Signed also by Sir Farquhar Buzzard and Sir Humphry Rolleston.)

FRIDAY, DEC. 7TH. 11.30 A.M.

The King has had some restful sleep and his general strength is maintained. Further investigation of the right side of the chest will be undertaken tomorrow day.

8.15 P.M. His Majesty has not had a restful night. A radiological examination was carried out this afternoon. Neither this nor exploration by puncture previously carried out, has disclosed any significant amount of pleural effusion. The general condition remains unchanged. (Signed also by Dr. H. H. Hodgson.)

SATURDAY, DEC. 8TH. 11.15 A.M.

The King has had some hours of sleep. The temperature is still raised on account of the local lung infection. The general condition is the same.

8.15 P.M. The King has passed a quiet day with sleep. The raised temperature persists, but the inflammation of the lung must of necessity be in its progress towards repair. (Signed also by Dr. H. H. Hodgson, Sir Humphry Rolleston and Sir Farquhar Buzzard.)

SUNDAY, DEC. 9TH. 11.45 A.M.

The King has had several hours' sleep. The persistence of the fever is having the inevitable effect of producing a certain measure of exhaustion. The pulse, however, remains steady.

8.30 P.M. The King has passed a quiet day, but there is no diminution in the exhaustion referred to in this morning's bulletin. The pulse remains steady.

MONDAY, DEC. 10TH. 11.30 A.M.

Although the King has passed a disturbed night, there has been some fall in the temperature this morning and there is also a slight improvement in the general condition. Anxiety, however, must not be forgotten.

8.45 P.M. His Majesty the King has had a quiet day. The signs in the lung have improved. The fever persists, though it is not so high as last evening. It is due to some return of the general infection, which necessarily affects the condition of the heart. (Signed also by Sir Farquhar Buzzard and Sir Humphry Rolleston.)

TUESDAY, DEC. 11TH. 11.15 A.M.

His Majesty the King has had several hours' sleep. The temperature remains high, but there is no further impairment of strength.

8.30 P.M. His Majesty the King has had a quiet day. There is no increase in the exhaustion, and the pulse remains steady.

WEDNESDAY, DEC. 12TH. 10.30 A.M.

The King has had some hours' sleep. There is improvement noted late last night is maintained, the temperature being somewhat lower and the general condition a little better.

4 P.M. (about). The slight improvement in the general condition noted this morning is maintained. A purulent fluid round the base of the right lung, removed by puncture this morning, and the drainage will be necessary. (Signed also by Dr. L. E. H. Whitby, Sir Farquhar Buzzard and Sir Humphry Rolleston.)

8.30 P.M. An operation on the King for the drainage of the right side of the chest has been successfully performed this evening. The condition of His Majesty is satisfactory. (Signed also by Sir Humphry Rolleston, Dr. Francis Shipway, Sir Farquhar Buzzard and Sir Humphry Rolleston.)

Oliver-Sharpey Lectures

ON AN EXPERIMENTAL STUDY OF CERTAIN VISCERAL SENSATIONS.

Delivered before the Royal College of Physicians of London

By E. P. POULTON, D.M. OXF.

FELLOW OF THE COLLEGE AND PHYSICIAN TO GUY'S HOSPITAL.

LECTURE II.*

Delivered on May 3rd, 1928.

CUTANEOUS OESOPHAGEAL REFLEXES AND COUNTER-IRRITATION.

HAVING dealt in the first lecture with the physiological mechanisms by which pain is produced, it is of interest to consider next how these may be affected by cutaneous stimulation, especially as counter-irritation has been employed from time immemorial in the relief of internal pain. The type of stimulation that Payne and I used¹ consisted in applying a turpentine stupe or mustard leaf plaster over the sternum, or rubbing with a pungent liniment such as lin. camph. ammon. B.P., or rubbing the skin with cotton-wool, a dry sponge, or the bare hand; but the actual method of stimulation does not appear to be important, since as marked results were obtained when the sternum was rubbed with cotton-wool or the bare hand as when a pungent liniment or a turpentine stupe was applied. At first bags were used which contained 10-30 c.cm. of air, amounts sufficient in some cases to produce vigorous activity on the part of the oesophagus, but not enough to cause actual pain. We found that the oesophagus became more active when the subject did the rubbing himself, and once or twice when the attention wandered and the experiment was forgotten rather unusual activity was also noticed. Increased activity was indicated by increased frequency and height of contraction and by a simultaneous rise in tonus, while with great activity large multiple contractions were seen.

The activity of the oesophagus depended to some extent on its activity immediately preceding the experiment. When the oesophagus was quiet, as was usually the case when there was but little air in the bag, stimulation caused immediate activity which tended to die down after stimulation or during the stimulation itself if this was prolonged. There was nothing specific in the type of activity caused by rubbing. In fact, a tracing might be obtained showing activity similar in all respects to what had been observed previously and for which there was no obvious cause.

When the oesophagus was already active stimulation sometimes caused a decrease in its activity. At other times the activity might remain unaltered and the type of contraction alone might be changed, but in this case the stimulation usually caused the activity to disappear in the end. In three out of the 17 experiments there was no obvious change in the tracing.

The effect of rubbing over the sternum in the case of a medical student inclined to attacks of indigestion is shown in Fig. 9 (A). The bag only contained 15 c.cm. but the oesophagus was rather active, since he had just been through an experiment with 40 c.cm. in the bag. The effect of rubbing was to cause a decrease in activity, so that only respiratory variations were shown. A wave was seen immediately the rubbing was stopped, which is rather a common occurrence; but otherwise the oesophagus remained absolutely quiet. Fig. 10 shows the effect of rubbing in my own case, when a bag in the lower oesophagus contained 30 c.cm. air. This was enough to produce considerable activity though no pain, and the movements of the oesophagus shown in the first part of the tracing resemble those of the same subject in Fig. 1. Rubbing

took place between the arrows, and was sufficiently severe to cause tingling between Σ and Σ . The effect of the rubbing was to change a fairly uniform tracing into one showing marked periodicity, so that it resembled to some extent that of an irregular Cheyne-Stokes breathing. After successive periods of waxing and waning there were no oesophageal movements at all for a period of 39 sec. Then movement began again, accompanied by a slight recrudescence of the tingling at Σ .

The same kind of result was obtained during proper counter-irritation—i.e., when the bag contained enough air to cause pain. Such a tracing in my own case is shown in Fig. 9 (B) with 40 c.cm. in the bag and with its end 12 inches below the teeth. Rubbing for 98 sec. took place between the arrows. Continuous retrosternal pain was felt before rubbing, and this disappeared during the rubbing and for some time afterwards; in fact, the rubbing felt "comforting." In this case the first effect of rubbing was to cause waning of the movements followed by a large multiple contraction, then a further diminution; but the interesting point about this tracing was that the diastolic pressure definitely fell. Thus before rubbing the lowest pressure was 20 cm. At the first period of waning it was 18 cm.; but the lowest value—viz., 13.5 cm.—was reached a few seconds after the rubbing was ended. As in Fig. 10, there was a completely quiescent period, in this case of 29 sec.

The fall of diastolic pressure and consequently of tonus provides the obvious explanation why rubbing made the pain less, since it means that the posture of the oesophagus had temporarily increased, and the tension on the pain-endings had fallen; but the other method of relieving pain is also shown in Fig. 9 (B), since there was an increase in the number of the contractions between the periods of waning, so that during this phase, too, the pain was less because the contracting muscle itself bore the strain instead of the pain-endings. This factor is exemplified in the large multiple contraction that occurred toward the end of rubbing, and the numerous small contractions after the rubbing was over. Hence it would appear that the pain is relieved by rubbing because the latter tends to produce an irregular Cheyne-Stokes-like type of rhythm. However, Fig. 9 (C) shows an experiment on myself where rubbing, again shown between the arrows, produced no lessening of the activity at all. In fact, the oesophagus became more active during rubbing, while the end of the tracing was very similar to the beginning. Pain is shown by descent of the lever, and during the activity the pain is obviously less, and particularly so during the rubbing; but pain came back immediately afterwards, because presumably the usual fall in tonus which, when present, persists for some time after the counter-irritation failed to appear.

What was the reason of this failure? It would appear to be due to the previous activity of the oesophagus. Thus in Fig. 9 (C), where the diastolic pressure actually rose, observations on the oesophagus had been carried out for 29 min. continuously before the counter-irritation experiment was undertaken. It has already been pointed out that the oesophagus tends to adapt itself to the presence of a bag by increasing its posture, and if at the end of the 29 min. stimulation by a bag the posture has reached its maximum value it is clear that no further increase can take place with rubbing. In Fig. 9 (B) the counter-irritation took place after the bag had been in situ for only 7 min., and it is interesting to note that when this experiment was repeated 15 to 20 min. later the fall of diastolic pressure was only 1.3 cm. instead of 6.5 shown in Fig. 9 (B).

In all we carried out seven experiments on counter-irritation which were successful in relieving pain. It was found that in five there was a fall in diastolic pressure, while in four there was some time or other an increase in the contractions. However, in one experiment neither of these features was present, so that our theory does not provide a complete explanation

BB

* Lecture I. appeared in THE LANCET of Dec. 15th.

of relief of pain by counter-irritation, nor does it explain why it occurred at the beginning of counter-irritation before the fall in diastolic pressure had time to take place. There must be a third factor, and this is probably psychological. The mere sensa-

be explained if a considerable dose of a histamine-like substance has been liberated into the system by the rubbing.

Our experiments on counter-irritation suggest a comparison with the mass reflex described by Head

and Riddoch³⁵ in patients with complete division of the spinal cord in the dorsal region in whom rubbing the skin of the lower limbs caused evacuation of the bladder with forced movements of the legs, &c. Danielopolu, Radovici, and Carniol³⁶ have published tracings of large single contractions of the bladder which followed stimulation of the skin in a patient suffering from spastic paraplegia due to syphilitic disease of the spinal cord. From our experiments on normals it is clear that the results are not so stereotyped as in the mass reflex, since they depend on such conditions as attention, length of previous stimulation, &c. The main difference, however, would appear to be that in the normal cutaneous stimulation does not invariably cause a big

single contraction. Very often there is an increase of the small contractions with rise of systolic and diastolic pressure, whereas where the tonus is high enough to cause pain we get this curious Cheyne-Stokes-like activity that has already been described.

SENSATION OF NAUSEA.

It is curious that on questioning various people there should be no very decided agreement as to exactly what sensation the term nausea or feeling of sickness should be applied. I asked one of my sons aged 9, where it was he felt sick, and he replied at

FIG. 9.

Oesophageal tracings in three experiments. Horizontal lines 0 and 40 cm. Rubbing over sternum between the arrows. Descent of lever indicates pain.

tion of the skin being rubbed hard by a muscular hand must divert the attention from the oesophageal pain felt deeply to the sensations felt on the skin itself, and so consciousness of the deep pain would be lost.

But it is not necessary to confine the rubbing to the overlying skin in order to obtain an effect on the oesophagus. In a number of experiments the skin was rubbed at a distance, and in Fig. 11, with 10 c.cm. air in the bag and W. W. P. the subject, rubbing the right calf with cotton-wool caused immediate activity with a slight increase of diastolic pressure to begin

FIG. 10.

with, while during the rubbing the bag produced a noticeable sensation in the throat.

When the skin over the sternum is rubbed activity of the oesophagus takes place presumably from reflex action; but is the effect on the oesophagus of rubbing the calf of the leg also an example of a reflex from a distance? Probably more than a mere reflex is involved, particularly when the rubbing is prolonged. Thus my colleague, W. W. P., has pointed out, what must be a familiar fact to many, that the violent scratching of an urticarial wheal, for example, may after the local itching has stopped, produce an increase of pulse-rate, feeling of exhaustion and dizziness in the head, breathlessness, with a sinking feeling in the stomach—various symptoms which can

once "in my throat"; and to Payne and myself this sensation felt in the back and lower part of the throat is so characteristic and localised that we have limited the term nausea to it. It is true that this sensation is often associated with a feeling in the pit of the stomach to which the term "sensation of sinking" or "emptiness" may be given, or with a frontal headache or with globus; but in any investigation of the subject it is essential to be precise as to the locality as well as to the quality of any particular sensation that I have stressed the actual connotation of these various terms in these lectures.

Our earliest investigations of nausea came about rather by chance. An experiment had been carried out on myself in which a bag containing 40 c.cm. of

air had been kept in the œsophagus for six minutes and had eventually caused much retching and been vomited. The bag was swallowed again and the volume of air was gradually increased from 10 c.cm. up to 30 c.cm. The activity, as shown in Fig. 12 (A), was moderate and alternated with periods of complete quiet. During one of the periods of activity a sensation of nausea lasting not much more than one second was signalled repeatedly, and was found to occur

FIG. 11.

during the relaxation phase of one of these peristaltic contractions, as shown by the white rectangles beneath the tracing. The air in the bag was then suddenly increased up to 40 c.cm., as shown in Fig. 12 (B). Both nausea, shown by the rectangles above the tracing, and pain in the throat, shown by the rectangles below the tracing, were signalled. The subject noted that there was a gradual transition of the sensation from nausea through a painful nausea to pain in the throat alone so that the sensations were really mixed, nausea or pain predominating as the case might be. Eventually pain in the throat was felt alone, though it proved rather difficult to determine the exact spot

at which the element of nausea in the sensation had come to an end. Three minutes later the pain in the throat disappeared and pain behind the sternum was felt alone; but there was no obvious alteration in the tracing at this time. A patient once described this throat pain to me as rasping, which I think is an apt simile. The appearance of nausea during peristaltic relaxation would suggest that the mechanism of its production is essentially the same as that of visceral pain, but that there is some specific sense organ

that reacts to a lower degree of tension than the pain-fibres, and occasionally both may be stimulated at the same time; but eventually, as elsewhere, pain is the over-riding sensation. The relation of nausea to pain in the throat is thus similar to the relation of touch to pin-prick on the skin, or of pressure to painful pressure on skeletal muscle. There is another point of interest. The sensations of nausea and pain in the throat in this experiment must have been sensations referred from the œsophageal excitation, for the bag was a good deal below the position where the sensation was felt. In fact, it would have been impossible to have retained it in the throat. We did find that the sensation of nausea was more readily produced the higher the bag was

situated in the œsophagus. In this connexion it is interesting that Boring²³ found that œsophageal stimulation tended to cause sensory effects at particular places, and he noted in one case that there was no visceral sensation between the upper part of the sternum and the throat; it was from the point of view of internal sensation, as if the neck was missing. No doubt people vary, since a medical student (N. I. K.), examined by Ride and myself, noticed nausea as low as the thyroid.

The sensation of nausea in our experiments was also described as a sensation of sinking in the throat, and if it is due to a slight tension exerted on specific end-organs in the œsophagus, it is to be expected that other means of producing this increase will also elicit the sensation. In this connexion I have a vivid recollection, while standing on board ship during a rough channel crossing, of feeling nausea at each descent of the ship while it disappeared completely during the ascent. I did not at the time analyse my feelings sufficiently in detail to determine the exact moment during the descent at which the sensation was felt; but Dr. G. H. Oriel informs me, both from his experience of transatlantic liners and of American elevators, that it is during the retardation towards the bottom of the descent that the sensation is experienced. This fits in quite well with the views just described, because the effect of this retardation on the elastic œsophagus which is suspended on a rigid framework—viz., the skull and vertebral column and bones of the lower limbs—would be to increase its tension in a longitudinal direction. A similar increase of tension would occur during the acceleration upwards at the beginning of the ascent, and I am informed that according to experience in quick lifts the ascent is a more potent cause of sickness than the descent. It should be mentioned that a peculiar sensation is often observed during the acceleration at the beginning of the descent as if the viscera were being left behind up above; but Dr.

FIG. 12.

Oriel is convinced that this sensation is not the same thing as nausea.

SENSATION OF SINKING OR EMPTINESS.

This was investigated by means of a rubber catheter which was passed into the cardiac end of the stomach and connected with a bellows so that air could be forced in rapidly. A rubber bag was also introduced into the stomach, and Fig. 12 (C D) gives the tracing from the bag. Between C and D 200 c.cm. were introduced into the stomach, and the effect was to produce a slight periodic rise and fall in the tracing, while the sensation of sinking of less than a second's duration is again recorded during the relaxation, but very near the lowest part of the tracing. At the

same time the subject, W. W. P., felt what he at first described as a desire to eructate. The feeling was as if there was some wind there which might come up, although it did not. Further analysis of the sensation leaves no doubt that it was felt behind the upper end of the sternum, and that it was identical with what has commonly received the appellation of "sensation of globus."

The rise and fall of the lever had quite a short periodicity, the intervals varying from 9 to 25 sec. with an average of 16. The time intervals were much too short for these changes to be considered as tonus variations. They must have been gastric peristalses, which might have originated in the cardiac part of the stomach, or perhaps were due to peristalsis occurring lower down, the pressure effects being conducted to the cardiac end of the stomach. At any rate, it is clear that the sinking sensation falls into line with that of nausea, and again may be considered as due to a slight rise of tonus, of the stomach wall this time, sufficient to cause tension on specific nerve end-organs, but not enough to cause pain. As is the case with nausea, the peristaltic contraction causes the disappearance of the sensation. It might be argued from Fig. 12 (D) that actually there was no increase of tonus, since the diastolic pressure was actually lower than before the air was introduced. However, the mere introduction of air with the consequent increase in the diameter of the stomach will itself increase the tonus, even though the pressure may fall. This is shown by the formula $T = pr$. In other instances where sinking was signalled the diastolic pressure was increased.

There are two observations which have a bearing on this question of the sensation of sinking. My colleague, W. W. P., has noticed that the sensation may be diminished by standing upright with the abdominal muscles braced. This would increase the intra-abdominal pressure and support the stomach wall, reducing the stretch by neutralising the intra-gastric pressure. A. E. Barclay²⁷ has made an observation in the opposite sense, since he found that the normal stomach may drop an inch or more when the patient smelt something which to him was nauseating, such as asafoetida. This sudden dropping must, I consider, be due to the abdominal wall being suddenly relaxed, and the result would be an increased tension on the structures in the stomach wall, which would cause the sensation of sinking. Evidently the relaxation of the abdominal wall may be so great that the venous return from the abdomen may be interfered with, since Barclay has observed that the patient has fainted a few seconds after the lower border of the stomach dropped by several inches.

The sensation of globus is a feeling of a lump which is often felt in the mid-line about the level of the clavicle, but my colleague has noted a similar sensation lower down behind the xiphisternum, particularly after a big dinner which "lies heavily on the chest." In our experiments globus has been frequently produced at the same time as the sensation of sinking, and the following experiment illustrates its production reflexly. In this case the catheter was passed into the stomach, while the bag to act as an indicator was placed in the lower part of the oesophagus, with its end about 15½ inches below the teeth. At first a level tracing was obtained showing respiratory waves and one rather larger wave which was probably a local contraction. Then 600 c.cm. of air was introduced through the catheter into the stomach, as described in the last experiment, which had been carried out just previously. The result was to cause a series of large contractions to pass down the oesophagus due to secondary peristalsis. The sensations of sinking and of globus were felt and recorded near the bottom of the depressions between the contractions. Hence the result of blowing up the stomach was not only to cause contractions in this organ, but reflexly to produce simultaneous contractions in the oesophagus, since in both experiments the sensations of sinking and of globus were recorded

between the contractions, and near the lowest points of the tracings. My colleague finds that in naturally occurring globus sensations an increase takes place during a deep inspiration, which would tend still more to stretch the oesophageal wall.

We have already given the name "gastro-oesophageal anti-regurgitation reflex" to the effect on the oesophagus of blowing up the stomach; but we have now found that it varies according to the condition of the oesophagus at the time it is elicited. In one experiment a catheter led to the stomach while the indicator bag in the oesophagus at first contained 50 c.cm. of air, enough to produce continuous pain and to prevent any contractions at all getting past the bag. The amount was then reduced and the first part of the tracing showed a continuous series of large contractions with pain felt during each relaxation. Then 600 c.cm. of air were forced into the stomach. This caused a complete upset in the rhythm of the oesophagus with disappearance of the large contractions, and there was also an immediate relief from the oesophageal pain. What happened was that the sudden increase of tension on the nerve-endings during muscular relaxation disappeared, and the steady tension during diastole which now remained was itself not enough to affect consciousness. This is, I think, a more likely explanation than that suggested previously²⁴ for the relief of pain in this type of experiment.

From the psychological point of view it is interesting to note that our experiments have suggested a specific type of sensation in three different parts of the upper alimentary tract. There is nausea felt in the throat, there is globus which is felt situated deeply at various levels behind the sternum, and there is a sinking or empty sensation felt in the epigastrium and due to the stomach. There are presumably special end-organs for these sensations; but as the stimulus increases these sensations give place to pain at all points.

The relation between these various sensations is well illustrated by a recent experience of my colleague W. W. P. He had a severe attack of indigestion after eating gooseberry tart at night. During the worst part of the attack there was a fairly intense "burning" sensation located very definitely at the level of the clavicles, relieved by swallowing. During spontaneous remissions the pain was sometimes replaced by a "globus" sensation. During the worst parts of the bout there was, in addition, at the xiphisternal level a gripping pain resembling in quality abdominal colic. It was sometimes brought on and was always intensified by swallowing. This latter pain was very like that caused by the incompressible bag described in the last lecture, and presumably indicated an area of high tonus which acted as an obstacle to the progress of the oesophageal peristaltic wave. The pain had such a colicky character that he thought at first it was abdominal colic until he considered the position which was clearly at the lower end of the oesophagus. This was confirmed later in the attack by the arrival of true colic pains with the typical mid-abdominal location.

These observations bear out a point I have emphasised on several occasions since our experimental work was carried out. The simplest way of diagnosing a sensation as oesophageal is to ask the patient to swallow. If the sensation is very slight it may be momentarily intensified, due to the tension on the nerve-endings in the wake of the peristaltic wave. If the pain is continuous and of moderate severity, the effect of swallowing will be to relieve it, as the peristaltic wave passes by and the part of the wall giving rise to the sensation becomes constricted. If, on the other hand, the pain is severe, the tone may be so high that the peristalsis is held up in its course. Swallowing will then produce a painful sensation of maximal intensity. As far as diagnosis is concerned the point is that swallowing always produces a change in an oesophageal sensation.

So far I have not mentioned the sensation of fullness which has bulked far more largely in the literature

than the sensation of sinking or emptiness. Curiously enough, W. W. P. and a student recently examined both experienced sinking and not fullness when air was blown into the stomach. Undoubtedly fullness does exist as a separate sensation, though possibly the two may not have been clearly differentiated in the description of gastric symptoms. If, as we maintain, sinking is due to a slight tension on specific nerve-endings of the stomach, then it would be surprising that fullness should be due to the same thing. Becher²⁸ suggested that gastric sensations were not due to the stomach, but to stretching of the abdominal wall, and he produced some evidence in favour of this. I suggest that Becher's explanation may account for the sensation of fullness, but that sinking is a purely gastric sensation.

Vomiting that so often terminates the sensations of a dyspeptic attack is due primarily to reflex contractions of the abdominal wall, though an observation of Ryle's shows that the stomach also plays a part.²⁹ Barclay³⁷ found that if the lesser curvature of the stomach was stimulated by electricity the abdominal muscles contracted, while the stomach remained stationary. Vomiting is not necessarily a painful process, as I can testify myself, when a bag was irresistibly pushed out of the oesophagus by an abdominal contraction without any sensation at all. On the other hand, I received one night a vivid impression how extremely painful vomiting may be. It was during an attack of acute dyspepsia from bad food, and the pain, which coincided with the abdominal contractions, was situated in the region of the xiphisternum, and was probably caused by the contents of the stomach being forced out through a closed cardia.

SEA-SICKNESS.

I am now in a position to put forward for your consideration what I hope may be regarded as a reasonable theory of sea-sickness, which rests partly on the work already described and partly on investigations by Dr. G. H. Oriel⁴⁰ recorded in THE LANCET, when he was surgeon to the Canadian Pacific steamships. His investigations have been on the biochemical changes that occur in this condition. Put shortly, they are that on comparing a normal day for the subject under investigation with a day at sea at the commencement of a storm there is on the latter day oliguria, an increase in the percentage of ammonia in the urine for each hour; ketone bodies appear in the urine, while the acidity—i.e., the hydrogen-ion concentration of the urine—is diminished, and the blood-sugar falls. All these results are observed before the onset of vomiting. From our present point of view the significant observation is that nausea is about the earliest manifestation of all, and on the day in question (Table I.) nausea was felt from 8 A.M. to 9 A.M. immediately on waking, while ketosis first occurred in the urine from 9–10 A.M. It is true that the percentage of ammonia in the urine passed at 8 A.M. was increased, but with the subject asleep it is impossible to say anything about the nausea at this time. On another occasion (Table VII.) he informs me that nausea was experienced from 1 to 4 P.M., while these biochemical changes were first noticed at 4 P.M.

We have seen that nausea may be produced by a sudden tension on specific end-organs in the oesophagus brought about by the retardation during the latter part of the descent of the ship, and the sensation of sinking in the stomach is presumably brought about similarly. I cannot say whether the acceleration which occurs at the beginning of the ascent is also a factor; Oriel informs me that the ship often hits a wave and there is a sudden jerk. On the theory here presented the nausea and sinking are the primary cause of sea-sickness, and these sensations act by reflexly inhibiting the normal movements of the alimentary canal with stasis of its contents. This is proved by Oriel's experience. For instance, a subject who took an ordinary lunch at 1 P.M. went to sleep between 2 and 4 P.M.; he then woke up with a headache, nausea, and ketosis, and with no desire

to take tea; he finally vomited up his lunch at 7 P.M., a 6-hour delay. Again, Oriel has found that his breakfast has reappeared at night, a 10–12 hours' delay. I think it is possible to explain the biochemical changes as the direct result of this stasis, since this would entail failure of absorption in the small intestine, and consequently carbohydrate starvation, hypoglycæmia, and ketosis. The hypoglycæmia and ketosis would probably increase the response of the oesophagus and stomach to the movement of the ship. Though proof of this is lacking, it is at least suggestive that sea-sickness occurs more readily on an empty stomach, and the sensations of nausea and sinking are closely related to, and often associated with, hunger. A vicious circle is thus established—viz., nausea, stasis, carbohydrate starvation, &c. If vomiting is once established the processes of nutrition become still more disturbed, and the patient may end in a state resembling that of diabetic coma. It is now easy to see why sugar in 3-drachm doses should be the most successful preventive treatment, as was found by Oriel to be the case. Much of it might remain behind in the stomach; but some of it would certainly get through into the intestine, raise the blood-sugar after absorption, and so break one link in the vicious chain.

On this theory it is possible to explain most of the well-known facts about sea-sickness.

Owing to the prevailing winds ships "pitch" from England to America and "roll" on the return journey. More people are sick going out, since the up-and-down movement of pitching is worse than the side-to-side movement of rolling. One of the best means of averting sea-sickness is to lie down flat. It is clear that this will not entirely do away with the effect of a bad pitch. Wearing a tight abdominal binder, or bracing the muscles of the abdominal walls to prevent sinking, are well-known prophylactics, and slow, deep respiration will act in the same way.

Other theories of sea-sickness have been dealt with by Oriel and need not detain us long. He found no evidence of any excessive stimulation of the labyrinth either by examining for nystagmus or by carrying out functional tests on the revolving stool in port and on board ship during the voyage. He himself met with three deaf mutes travelling together for the sake of company—one of them editor of the *Deaf Mutes' Gazette* of America. One of these three was sick, though it must be admitted they were in the tropics at that time when sickness on board ship was due to other causes. All these points are against the labyrinthine theory, although it may play a part in certain cases. Similarly, he has dismissed the neurotic or auto-suggestion theory. Undoubtedly people are sick as soon as they reach the ship or when travelling on perfectly calm water along the River St. Lawrence. Over-feeding, constipation, migraine, and pregnancy are all well-known predisposing causes; but sea-sickness is too definite an entity to be explained in any such way. Finally, we have the two theories of cerebral anaemia on the one hand, and cerebral congestion on the other. Although many of the facts I have enumerated fit in satisfactorily with either of these theories, there is evidence for a primary nausea, but not so far as I know for these other possibilities. In the present state of our knowledge it is hardly worth speculating on a possible fibrosis of the alimentary canal that may render old people immune to sea-sickness, or why babies are free; it is presumably owing to the jerking that people, and especially children, are occasionally sick on railway and motor-car journeys. It is quite clear that certain other factors may perhaps be present in these relatively uncommon cases; but this hardly affects our view of sea-sickness which may attack one-third of all the passengers on a voyage.

CARDIAC PAIN, ANGINA PECTORIS.

It may seem presumptuous in a short half hour even to attempt to say something new on the subject of angina pectoris; but as in these lectures I have

so far dealt, almost exclusively, with sensations in the throat, chest, and upper abdomen, it would seem strange to confine myself entirely to the upper alimentary tract as their cause, and spend no time at all on that intensely interesting subject, the cardiovascular system, especially as within the next fortnight we shall be celebrating and meditating on Harvey's great discovery. Further, as a physician who has had the privilege, though a doubtful one, of experiencing these pains himself, and whose interest has been naturally aroused in this subject, I feel that I may have a special claim on your attention. Since these lectures are primarily experimental, I shall only mention theories of angina pectoris that have been brought forward up to the present time, so far as they have a bearing on the work described. One such theory has been advocated strongly by Verdon,⁴¹ who claimed that angina pectoris is due to the disturbances of the nervous mechanism of certain spinal segments, arising not in the heart, but usually in the stomach or oesophagus. These organs become distended with gas, and the tension of the muscular coat stimulates nerve-endings which spread to the spinal cord and give rise to the anginal syndrome. Of course it is true that acute dilatation of the stomach may reflexly produce a serious and perhaps fatal cardiac disturbance, and symptoms may be relieved by the passage of a stomach-tube; but there are observations by Payne²² and myself on two cases of ordinary angina which certainly negative this explanation as a universal cause of the condition.

E. T. K., a farmer, aged 42, had for some years complained of pain in the upper part of the chest on the left side after exertion. It used to pass down the left arm. He was a stout man of exemplary habits. There was no history of alcohol. X ray showed that the heart was greatly enlarged to the left side, and the stomach seemed somewhat displaced to the right. There was no valvular disease.

An oesophageal tracing was taken. The bag was 3 cm. above the dome of the right diaphragm. The diastolic pressure was 1 cm. falling to 0. The patient then took some exercise and slight pain followed. The mean pressure had fallen to -1 cm. and there were still no contractions. It was noticed that swallowing produced very little effect on two occasions; but on another occasion, after swallowing, a rise of 10 cm. pressure was observed.

Another patient who had mild anginal attacks after exercise used to be able to get rid of his pain by making a loud roaring noise—i.e., expelling his breath under pressure through a partly closed glottis. It was observed on the X ray screen that this manoeuvre was followed by an increase in the volume of the gastric air bubble which is the reverse of what one would be led to expect on Verdon's hypothesis.

It was more or less by chance that Campbell and I⁴² came to make observations that we think have a definite bearing on this subject.

The patient was a man who was being treated in the oxygen chamber of Guy's Hospital. His age was 66 and he was admitted for breathlessness and pain in the chest on Feb. 25th, 1924. He had always had good health till April, 1922, when he had to go into hospital for a time. He returned to his work as a carpenter, continuing under medical treatment, but had to give up work finally in July, 1923, for breathlessness and pains in the legs. He felt

much better when he was discharged but was not able to go back to work. On readmission he complained of orthopnoea and short acute attacks of breathlessness at night; also of giddiness, insomnia, and loss of weight. He had attacks of pain which were brought on by exertion—the pain being substernal and precordial and a little down both arms—especially if he walked after meals. He was diagnosed as myocardial disease. His heart was enlarged both to the right and to the left, the maximum transverse diameter being 7½ inches. There were occasional extrasystoles but no bruits. There was a little oedema of his feet on admission, but none when he went into the oxygen chamber; there was no albuminuria. There were no abnormal physical signs in his chest and there was little sputum, although he had a cough. His breath could be held 15 seconds.

This patient was investigated by means of a closed circuit apparatus based on Douglas and Haldane's⁴³ apparatus; it is shown diagrammatically with certain modifications in Fig. 13. The patient breathes through inspiratory and expiratory valves A. During expiration the air passes upwards through a vessel n, from which a sample of air may be taken for analysis of the CO₂ percentage, then through

FIG. 13.

a large tin containing soda lime and flake caustic soda in order to absorb the CO₂, and then into the spirometer (C), which rises, and the extent of the rise is indicated by the fall of the needle which is marked on the drum (D). During inspiration the air passes out of the spirometer through the inspiratory valve back into the lungs; at the same time an amount equal in volume to that which is absorbed by the lungs is drawn from the Douglas bag (E) through a meter and water valve into the closed circuit, so that the pressure remains constant. While the amount of the pulmonary ventilation can be measured from the drum record, it can also be determined by a work adder (F) as used by Prof. F. G. Benedict, by means of which the volumes of successive expirations are added together. The CO₂ output is calculated from the pulmonary ventilation and the CO₂ percentage is determined at frequent intervals. Actually the inspiratory and expiratory valves were attached to a face-piece which was fitted airtight to the patient, and held in place by straps attached to a canvas cap. The valves were attached to the apparatus by corrugated rubber tubing, so that the patient's respiratory exchange could be determined while he was sitting at rest, doing muscular work, and again sitting at rest until the values had again reached the resting level.† The muscular exercise consisted of stepping up and down a height of 13 inches by means of two steps, and this was repeated 18 times in three minutes.

Observations were made on a number of patients and normal students, and, as might be expected, level tracings were obtained on the drum; but in the case of the patient with myocardial disease a drop in the tracing commonly occurred during the exercise. For instance, in Fig. 14 (B), where the arrows mark intervals of a minute, the drop began after the

† It is hoped to describe in the Journal of Physiology a form of the above apparatus more suited for ordinary metabolic work.

first $1\frac{1}{2}$ minutes of work (W), and reached its maximal value after the third minute. The tracing gradually regained its normal level during the first two minutes of rest (R), after the exercise was finished. This meant that during the exercise the spirometer rose, and this could only have been due to an increase in the volume of air in the circuit. It was noticed at the same time that the pressure in the circuit rose slightly, and the intake of oxygen through the meter fell to zero. Since the CO_2 was being absorbed all the time the only place where the extra volume could have come from must have been from the patient himself. The volume in question amounted to about 1400 c.cm., but actually it must have been more than this, because the patient was absorbing oxygen all the time from the apparatus and yet no oxygen, or very little, was coming in through the water valve. If the normal amount of oxygen was absorbed by the lungs calculation shows that the O_2 absorbed from the circuit would be about 1200 c.cm.; but this figure is probably too high, so that actually during the work the patient expelled from his chest a volume intermediate between 1400 and 2600 c.cm. One possible explanation was that the patient's chest had fallen in, so that he had expired air from the lungs into the apparatus. This possibility was tested by recording by means of a stethograph the movements of the patient's chest on the drum below the respiratory tracing. Every time the patient stepped up there was a rise in the stethographic tracing; but the general level of the tracing remained constant, in spite of the fact that air was being expelled from the

expelled from the lungs because they were actually engorged with blood and perhaps at the same time there was some cardiac dilatation. If this is the case then we have found a method of measuring the efficiency of the pulmonary circulation which may obviously be of some importance in the future investigations of circulatory problems.

FIG. 15.

FIG. 14.

chest during the later part of the work. In fact, the only event that altered the stethographic tracing was when the patient sat down, as shown at R, which upset the adjustment of the apparatus. Clearly there was no falling in of the chest, and I think we may assume that if there was no falling in of the chest there was also no rise in the diaphragm, though we have no direct evidence on this point. Another possibility that suggested itself was that the air was

of a single patient, were it not for some very interesting evidence of Dr. G. P. Crowden's, which has been recently communicated to the Physiological Society. I will describe three of his results. A radiogram of his own chest was taken with the breath held at the end of a normal inspiration. A second radiogram was taken also at the end of a normal inspiration, but with the breath held and an extreme effort made to breathe out against obstruction. This is Valsalva's well-known experiment, and the result was that the pulse could not be detected at the wrist, though on the X ray screen it was observed that the heart was making slight movements. A third radiogram was taken at the end of a normal inspiration with the breath held, and an extreme effort made to breathe in against resistance (Müller's experiment). The effect of Valsalva's experiment was to cause a diminution in the size of the heart shadow, while the root shadows were much less dense than at the end of normal inspiration when no effort was made to expire. This can only have been due to much of the blood having been pumped out of the chest, while it was not able to enter from the venous reservoirs outside owing to the high intrathoracic pressure. In Müller's experiment, however, the shadow of the heart was much increased in size, being practically twice as large as in Valsalva's experiment, while the dark root shadows spreading out into the lungs indicated engorgement of the pulmonary vessels. If such a great alteration in the distribution in the blood is obtained in such simple experiments on a healthy subject our result is perhaps not so surprising after all.

Another point of interest is shown in tracing A of Fig. 14. In this case the patient had performed the same exercise; but it was on the third day of his treatment in the oxygen chamber. It is to be noticed that the drop was small, and probably did not amount to more than half a litre of air. A number of similar observations were carried out on this patient when he was under, and when he was not under, the influence of oxygen, and results agreeing with the foregoing were always obtained. Another observation made that has a bearing on the present discussion. The patient told us that he felt precordial pain during the exercise, and in one experiment this began just at the beginning of the second minute and coincided with a big drop in the tracing, which corresponded to about 1500 c.cm. No further systematic observations were made on this phenomenon of pain at the

time; but two years later he was again examined by Dr. Campbell, because it was thought that another way of proving that engorgement of the lungs was caused by exercise would be to determine the vital capacity which would be diminished under the circumstances. Before exercise the vital capacity was 3 litres, while immediately after the pain began the value was 2 litres. Immediately after the pain had disappeared the value was 3.1 litres. A similar diminution but not so large was noticed on a second occasion. In this connexion it is to be noted that Williamson⁴⁴ found by X rays that the heart was dilated immediately after exercise in four out of ten patients who on clinical grounds showed evidence of circulatory insufficiency, while normally the cardiac shadow diminished immediately after exercise.

The accumulation of blood in the lungs means that the right side of the heart has delivered the blood, but that the left side of the heart has failed to get rid of it. What is this but acute left-sided failure; may it not be accompanied by strain of the right ventricle in its attempt to keep the blood moving on? May not the pain be due to this strain?

In Fig. 14 and in another similar experiment the pulmonary engorgement began after about the first minute of exercise, and relief only began when the patient sat down after the exercise was finished. However, Starling showed that dilatation of the heart with lengthening of the muscle-fibres stimulates it to increased activity, and an experiment is shown in Fig. 15 in which during the exercise left-sided failure and recovery followed one another in quick succession, since there are three separate falls in the tracing representing volumes of 450, 300, and 450 c.cm., each followed by a return to the normal level.

The exact relation of the cardiac pain to the circulatory changes described requires much further observation. While the onset of pain has been observed to coincide with the fall in the tracing, it began on one occasion when the tracing had regained its normal level after recovery was complete. Cardiac pain might be expected to be analogous to other visceral pain, so that it would be caused by an increase in the muscular tension during diastole, which would depend on the same two factors of diastolic pressure and radius of curvature. Though cardiac pain might be most commonly felt during pulmonary engorgement and cardiac dilatation, it might also occur after recovery if the diastolic pressure became very high.

These experiments raise fresh problems for consideration. Is there such a thing as an acute right-sided failure lasting a few seconds associated with an accumulation of blood in the liver and large veins perhaps also accompanied by strain of the left ventricle with its characteristic pain? Certainly in my experience there are at least two distinct kinds of cardiac pain. There is a sharp, what the psychologists might call "bright," definitely localised pain on the right side of the chest very often at the inner end of the third right costal space. Then there is the ill-defined diffused constricting sensation which is felt at the top of the left side of the chest and simultaneously down the arm. Is the left-sided sensation due to left-side strain associated with acute right-sided failure and the right-sided sensation with a right-sided strain due to left-sided failure? I have used the word "acute" advisedly, since it is a well-known fact that typical angina does not occur in chronic gross heart failure, and as the heart failure improves the angina is increased. The patient that I have described illustrates this to a marked degree. He has recently been in hospital again owing to his anginal pain, while some weeks previously he was laid up with pain and swelling in the legs, but no pain in the chest. It may be that in gross cardiac failure with oedema the heart gives up the struggle, and does not work hard enough to produce its characteristic pain.

Let us consider the bearing of these facts on the treatment of angina. I can only say that in most cases of angina amyl nitrite acts like a charm; the pulse is quickened, the face is flushed, and the head swims, and at this point the pain rapidly fades away.

It is well known that the blood pressure is not always raised in an attack, nor does it fall before the relief of pain by amyl nitrite. May the latter not act by stimulating the left side of the heart to renewed efforts? But if this is the case, is it really wise to attain the goal by whipping a flagging horse? It was in some such strain as this that I wrote on the pathology of angina in the last edition of the text-book for which I am responsible, and I was much interested to receive a letter from a doctor shortly after the appearance of the book in which he stated that he had attended a lady for angina pectoris—it may have been coronary embolism—and that a full dose of amyl nitrite had failed to relieve her symptoms, and on administration of a second dose the patient died. If a moral may be drawn it is that a patient who has had angina should live within his cardiac reserve. He has many opportunities from the slight sensations he experiences of judging when he is overdoing things. It is better not to rely on drugs.

Some very interesting observations were brought forward at a recent meeting of the Physiological Society by Bramwell. He administered amyl nitrite to himself and then measured the effect on the electrocardiogram and on the sphygmogram from the carotid taken by a delicate optical method. The results are fascinating in the suggestions they raise, but tantalising because they contain no absolute proof of these suggestions. According to these experiments, amyl nitrite causes a diminution in the time occupied by the cardiac cycle; in other words, the heart is quickened. There is an increase in the rate at which the blood is expelled through the aortic valves. There is also an increase in the rate of the isometric contraction of the heart; but what is especially suggestive is that the maximum effect on the isometric contraction is reached before the maximum effect on the rate of ejection or on the length of the cycle. Is there not a suggestion here that amyl nitrite acts by stimulating the heart? Since writing the above Dr. Anrep has informed me that his experiments have proved that amyl nitrite definitely stimulates the cardiac muscle.

I think it possible to suggest a treatment for at any rate mild angina (angina minor) by considering Crowden's experiments, since it was a forced expiration against resistance that emptied the blood from the chest and diminished the size of the heart. One of the patients that I have already described obtained relief from his angina by making a roaring noise. I have myself successfully got rid of mild left-sided pain by this means. The immediate effect of the forced expiration is often instantaneous, and I think this method is often effective in preventing the return of the pain. I have one recent observation on right-sided pain where this procedure definitely made the pain worse, but the latter disappeared on taking a deep inspiration—i.e., the reverse of the left-sided pain.

So far I have treated the subject of cardiac pain as being due to an adequate stimulus, which is distensible. I should like to quote⁴⁵ what must be the earliest proof that other kinds of mechanical stimulation of the heart do not produce any effect on sensation. It was the case of a young nobleman who had had his ribs broken, and on the left side an abscess had formed and left a large gaping wound; he came to London when 18-19 years old. King Charles I. heard of it, and asked Harvey to see him and report on the case. Harvey found an extensive ulcer in the man's side—

"into which I could readily place three fingers and a thumb. Which done I straightway perceived a certain protuberant fleshy part, affected with an alternating extrusive and intrusive movement; this part I touched gently. Amazed with the novelty of such a state, I examined everything again and again, and when I had satisfied myself, I saw that it was a case of old and extensive ulcer, beyond the reach of art, but brought by a miracle to a kind of cure, the interior being invested with a membrane, and the edges protected with a tough skin. But the fleshy part (which I at first sight took for a mass of granulations, and others had always regarded as a portion of the lung), from its pulsating motions and the rhythm they observed with

the pulse—when the fingers of one of my hands were applied to it, those of the other to the artery at the wrist—as well as from their discordance with the respiratory movements, I saw was no portion of the lung that I was handling, but the apex of the heart covered over with a layer of fungous flesh by way of external defence, as commonly happens in old foul ulcers.

"Instead of a verbal answer, therefore, I carried the young man himself to the King, that His Majesty might with his own eyes behold this wonderful case; that, in a man alive and well, he might, without detriment to the individual, observe the movement of the heart, and, with his proper hand even touch the ventricles as they contracted. And His Most Excellent Majesty, as well as myself, acknowledged that the heart was without the sense of touch; for the youth never knew when we touched his heart, except by the sight or the sensation he had through the external integument."

I have quoted this case to illustrate the value of a clinical observation on the part of one who has been handed down to posterity, primarily, as an experimentalist. There is a movement nowadays that might be called "Back to clinical medicine," and which is apt to treat the experimental side of the subject with scant respect. I would urge that to place these two methods of observation in antithesis is a mistake. Certain it is that the application of the so-called experimental method to the alleviation of disease requires the most careful clinical observation, and it is not less certain now, than it was in Harvey's day, that clinical observation must be incomplete without further experimental study.

SOME ASPECTS OF DENTAL SEPSIS,

FOCAL AND RESIDUAL.

By TALLENT NUTHALL, M.D. LOND.,

MEDICAL ASSISTANT, GUY'S HOSPITAL.

A careful search must be made for any focus of infection, such as a tooth, and, if one is found, it must be eradicated.

A SENTENCE such as this is almost certain to occur in any article or lecture on those diseases which we now regard as the results of bacterial toxæmia. When the teeth are incriminated the focus is believed to be completely eradicated by the extraction of those teeth. Yet it is evident from the results obtained that extractions are by no means a certain cure, and that many patients are no better and some are worse off than they were before. During the last 10 or 20 years so many teeth, innocent and guilty, have been sacrificed that it is coming to be fairly generally held among the lay population that a visit to the doctor is most likely to result in their being advised to part with some or all of their teeth. They see on all sides the dentures, conspicuous or otherwise, of their friends, and note that while some fortunate ones have been cured, many remain crippled. One meets with great divergence of opinion among the profession, and nowadays to mention dealing with the teeth as a cause of focal sepsis is to excite mildly derisive smiles amongst an audience of medical men. There is a general feeling that the thing may have been overdone, that there are factors which are not yet understood. There does seem some reason for believing that the procedure is becoming discredited not only among the lay population but also among the medical profession.

In this article the results of bacterial toxæmia are taken to include infective arthritis, sciatica, and neuritis generally, lumbago, and the so-called fibrositis. Where only one is mentioned the rest are implied and are only omitted to save space. Furthermore, the subject is dealt with entirely from the medical point of view, and purely dental aspects of the question are not considered.

The Teeth in Themselves not the Source of Trouble.

No one will deny that the teeth are very frequently the primary site of the infection, but it is obvious that if the infection is confined to the teeth and the teeth only, generalised symptoms are unlikely to result. A carious tooth is an infected tooth, and many teeth are the subjects of pulpitis, but neither of these conditions will in itself give rise to arthritis or fibrositis. In fact, it is not the infection of one or more teeth that matters. What does matter is the extension of the infective process into the neighbouring structures, first the periodontal membrane and—more important still—the alveolar bone. Both are highly vascular and there are plenty of blood-vessels to carry into the system the toxins which result from bacterial metabolism. Over and above this, the structure of the alveolar process, loose and with a multiplicity of cancellous spaces, is a particularly favourable medium for the growth and spread of organisms. When this invasion takes place the area of infected tissue is enormously and progressively increased, absorption of toxins occurs on the grand scale, and generalised symptoms appear.

How Infection Occurs.

There are three means of infection: (1) via the pulp and root canal; (2) by direct extension from the periodontal membrane; (3) by direct extension from a fragment of root left behind after extraction.

The first commonly results in the formation of an apical granuloma or abscess; that is to say, the process may be localised for variable periods of time. There may, however, be no localisation but an infection spreading into the alveolus without the

formation of any line of demarcation such as is necessarily implied by abscess formation.

The second is the commonest route. Considering the vast number of teeth which show signs of periodontitis, abscess formation is rare. The process is one of direct extension, first of all in the membrane and thence into the bone.

Every now and then during extraction a fragment of root is broken off and left behind. It is usually already infected, but in any case it becomes so before the socket has healed. After a lapse of time either an abscess forms or else a diffuse infective process starts and spreads in the alveolar bone.

Infection may also occur via the blood stream. It has been suggested that the organisms are carried by the blood stream from some other organ to the teeth, which they apparently select as their site of operation. This seems to be far less frequent than the other routes.

The Role of Pyorrhœa.

Many authorities hold that pyorrhœa is of little or no importance in the causation of arthritis and allied conditions, but the question seems to be entirely one of the extent to which the pyorrhœa has advanced. Strictly speaking, pyorrhœa is a symptom of an infection of the gingiva and superficial alveolus. So long as it is confined to superficial regions from which there is free drainage into the mouth, the effects on the system are likely to be those produced via the tonsils or the gastro-intestinal tract. Directly, however, the pyorrhœal pockets involve the periodontal membranes the way is open for direct extension of the infective process in the membrane and thence into the alveolar process.

Dental Skiagrams and their Import.

Apical abscesses, dental cysts, and granulomata are all striking features when seen in dental radiograms. Dead teeth can usually be recognised by changes in the pulp cavity and root canals, which become less defined and may be lost altogether. Periodontitis, when marked, is unmistakable. The healthy periodontal membrane appears in the negative as a fine, clearly defined black line between the tooth and the lamina dura. In periodontitis it is widened, sometimes along the entire surface of the tooth, but more often in parts, so that its outline becomes irregular and uneven. Proliferation of the lamina dura also occurs, so that the periodontal outline may vanish more or less completely, and the shadow of the tooth as a whole loses definition. More important, though less easy to recognise, are the changes which result from infection in the alveolar bone. In a radiogram the cancellous structure of the alveolar process can be clearly seen. The fine trabeculae appear in the negative skiagram as light or white lines, crossing one another at angles and enclosing minute angular spaces which appear darker. When the bone is infected, these appearances change. The details become blurred; in places the trabeculae are thickened and the small angular spaces are replaced here and there by rather larger, rounded spaces which appear almost black. These are minute areas of rarefaction, which are always to be seen in the neighbourhood of the apices of teeth which show periodontitis. They are, in fact, the earliest evidence of the invasion of the alveolar bone by an infective process. Larger oval or irregular-shaped areas of this rarefaction are often to be seen in the interdental septa or just deep to the alveolar margin where absorption is taking place; these denote infection of longer duration. Another common rarefactive change is an irregularly circular or oval area spreading from or around the apex of an infected tooth, an area which is more radioparent than healthy bone and appears greyish in colour or less dense than the surrounding tissue. In it the cancellous structure is less sharply defined and may be unrecognisable. This appearance is caused by a diffuse infection of the alveolar bone, spreading away from an infected apex or root without the formation of a classical abscess or any limiting process. Several such areas may be seen, most often in connexion with the premolar teeth. In time they coalesce, and eventually

a large part of the alveolar process may be so affected. When the whole or a complete half alveolus is infected the condition is not so easily recognised in the films, but the loss of detailed structure and lack of contrast and density should reveal it. If such an area be explored it will be found spongy and soft, instead of hard and firm like healthy alveolar bone.

Changes in the nature of sclerosis may also be frequently seen. As mentioned above, the lamina dura in the neighbourhood of infected periodontal membrane commonly undergoes proliferation. There may be areas of sclerosis in the interdental septa or adjacent to the apices of the teeth. These areas may replace the whole of the normal alveolar process between two teeth. They appear as almost structureless whitish patches of irregular shape and variable size. By some they are regarded as attempts at repair or defence, but it seems equally reasonable to consider them as early reactive changes evoked by the invading micro-organisms.

The Contribution of Bacteriology.

Although there can be no doubt that a suitable vaccine is one of the most valuable means of treatment, it might be well to ask whether bacteriological investigations can help us in diagnosis. A streptococcus is almost universally held responsible for the lesions we are considering, but it is not possible to incriminate any particular type of streptococcus. It is reasonable to suppose that any streptococcus, given certain opportunities and a suitable environment, is capable of causing disease. The *Streptococcus hemolyticus* and the *Streptococcus viridans* especially are the two which seem most active in producing arthritis or any infective condition. It is not possible to argue, however, that the finding of a streptococcus in a culture from a pocket or from the apex of an extracted tooth is to be regarded as evidence either that an infective process is at work or that the organism so isolated is causal. Swabs from any structure in the mouth will almost always yield a growth of streptococci of some sort, mixed with other organisms. There are, however, two ways in which bacteriological investigations can help towards forming an opinion. One is when the cultures made from a pocket give a pure growth of a streptococcus, and especially *S. viridans*, to the exclusion of other organisms. The second is when the patient's serum can be shown to contain agglutinins or other antibodies specific for the organism which has been isolated. Unfortunately, this can only be demonstrated in a small proportion of cases, but when it does occur it may reasonably be argued that infection is taking place and that the organism agglutinated is the offender. The converse argument—that the absence of demonstrable antibody formation denotes a deficient resistance on the part of the patient—cannot be regarded as equally convincing.

The Soil.

The difference in the way in which patients react is a striking feature of these infective conditions. In the imperfect state of our knowledge we explain this as being a question of resistance on the part of the patient. The great prevalence of arthritis, fibrositis, and the other results of focal sepsis seem to point to the conclusion that there is less resistance now among the general population than there was a generation ago. The title given by Pern to his article the *Streptococcus—the Biggest Menace to Mankind*,¹ has a very real application in these days when one considers the very large amount of incapacity and illness caused by this organism. Some patients show a surprisingly high resistance to a degree of infection which would speedily disable others. To give an example:—

A man, aged 62, with rosy cheeks and a healthy appearance, who had always led an active out-of-door life, complained of pain and stiffness in one shoulder and in his neck. This had been increasing since a fall a short while before. He was proud of the fact that he had an almost complete set of his own teeth. Radiograms showed that he

¹ Med. Jour. Australia, 1922, II., 518.

had seven chronic apical abscesses which must have been developing for years. Yet his general condition was extremely good and he showed none of the symptoms—such as loss of colour, earthy complexion, depression, lassitude, and incapacity for physical exertion—which are usual in focal infections. His resistance was so great that it was not until bruising from his fall slightly damaged the shoulder-joint that the extensive infection in his mouth was able to give rise to any secondary effects.

As an instance at the other extreme, a woman of 42 came with a six months' history of acute sciatica which nothing relieved. She had had several attacks of "P.U.O.," labelled malaria as she had lived in East Africa. She looked sallow and ill. On radiographing her teeth, I found one large abscess at the apex of an upper molar tooth.

Resistance to the results of focal infection, therefore, is a very variable factor in different people, and one person may carry a focus of infection in his mouth to the end of his life without showing any apparent results from it, while a far lesser degree will speedily disable another. As the resistance varies, so does the recuperative power.

Methods of "Eradication" and Where They Fail.

When it has been decided that infection of the teeth is the cause of a patient's lack of health, the various procedures commonly adopted are:—

1. Complete clearance of all the teeth. This may be carried out forthwith without any previous radiographic or other scientific examination, on a "hit or miss" principle which has little to commend it.

2. Extraction of the obvious offenders, teeth with granulomata or apical abscesses.

3. Extraction of all teeth which show any skiagraphic sign of infection after careful consideration and previous examination.

4. Extraction of "dead" teeth only. The number of workers who confine their attentions to dead teeth and strongly oppose the extraction of any tooth which is still vital, whatever may be the radiographic appearances, is a large one, surprisingly large when one considers the inference to be drawn from such limited procedure. This inference is that only dead teeth can be so infected as to give rise to disease. One constantly meets with the expression of this view, not only in this country but also in reports on radiograms made in the United States, and when not expressed it is implied by the fact that only dead teeth have been dealt with. I feel that this opinion is in such strong opposition to the facts that I was greatly tempted to head this paragraph "The Dead Tooth Heresy." Nothing, in the present state of our knowledge, affords any grounds for the supposition that a tooth must be non-vital before it can be concerned in focal sepsis.

Any of these procedures may prove successful. Any of them may fail, and the reason for failure is the same in all the groups. It is because the original treatment is not radical enough and residual infection is left behind. Where a solitary apical abscess, for example, is dealt with by simple extraction, it is reasonable to expect that the resulting drainage, followed by granulation and healing of the bone, will put an end to the trouble, but when there is diffuse infection involving the apices of two or three teeth or one-half of the alveolar process, then it is not conceivable that the mere extraction of the teeth will in all cases put a stop to the infective process. Most of the softened infected bone is left behind, and in it enormous numbers of organisms continue to multiply and pour their poisons into the blood stream almost as freely as before the teeth were extracted. The gum heals with remarkable rapidity. Even an abscess cavity, left when the tooth has been extracted, is quickly covered over by dense gum tissue before it can be filled with healthy bone. Owing to this rapid healing, the length of time during which drainage can take place is very limited and, where a large area is involved, the amount of drainage must be almost negligible.

The Logical Treatment.

If we are agreed that a certain group of symptoms is due to an infective process, the logical treatment is obviously the removal of the source of that infection.

If, in the condition under discussion, we cannot bring about this end by simple extractions, we must take such further steps as will ensure it as far as possible. This means that, in addition to extraction of teeth, any *unhealthy bone must be removed also, or, in other words, a partial or complete alveolectomy must be performed.* This sounds a formidable undertaking both for the patient and for the operator, but it is not in fact so severe as it sounds. Having submitted many patients to it and from personal experience as well, I can say that the general effects in the way of shock, &c., are slight, the amount of pain little if any more than after ordinary extractions, while healing and consolidation are rapid and dentures can be made to fit quite as perfectly as after simple extractions.

Briefly stated, the operation consists in removing the teeth, elevating a flap of gum tissue, excising the interdental septa, and removing all soft, spongy bone from round the tooth sockets. When hard and healthy bone is reached, the rough edges are smooth with a burr and the flaps of gum stitched together. Where only a small area of the alveolus is involved it may be possible to remove the unhealthy bone by way of the open socket or by removing quite a small portion of the buccal surface of the alveolus. In any case, the extent of the procedure is determined by the point at which healthy bone is encountered, but the important part of the proceeding is to leave behind no unhealthy bone.

Residual Infection.

We all have patients who have had their teeth extracted without experiencing any improvement of the condition for which the extractions were done. This disappointing result is most common in infective arthritis. It may be that in a certain number the condition of their teeth was not responsible for their trouble, but I believe that many such results are due to residual infection, and this belief is confirmed by radiograms taken of the edentulous jaws. Any or all of the bone changes resulting from infection may be found persisting in the alveolar processes after the extraction of teeth: tooth sockets which have never consolidated and are little more than chronic bone abscesses, areas of sclerosis, and—most frequent of all—areas of rarefaction, large and small, diffuse and limited. If we accept these radiographic appearances as evidence of infection, then we cannot be surprised that the patients do not improve. To cite a typical case:—

A man aged 44, who had had no illnesses, suddenly developed arthritis in one shoulder and one toe-joint. All his teeth were extracted, but the condition progressed and gradually affected other joints. A year later the tonsils were removed, but this caused no cessation in the progress of the disease. When seen two years after the beginning of the arthritis, practically all his joints were involved and he was a cripple. Radiograms of his edentulous jaws showed that the whole of his upper alveolar process was still infected, hardly any normal alveolar structure being visible, while the lower alveolus showed numerous areas where infection still persisted.

There is another type of residual infection which was first described by Eyre. Normally, the occlusal surface of the alveolar process appears in the radiograms as a sharply defined, smooth edge when consolidation is complete after the extraction of the teeth. One frequently sees small areas where the smooth edge is replaced by a number of minute, irregular, bony projections resembling the teeth of a fret-saw. These areas are due to persistent infection deep to the gum, and Eyre has demonstrated the invariable presence of the *Streptococcus viridans* in cultures made from these bony spicules. Such a state of affairs is clearly capable of maintaining a supply of bacterial toxins in the general circulation.

Alveolectomy versus Extractions.

This does not mean that we should advise alveolectomy, partial or complete, for every patient who is suffering from the effects of focal sepsis arising in connexion with the teeth. We know that in a large number of cases simple extraction of the infected teeth is sufficient to bring about a cessation of the trouble. Patients vary in their resistance and in their

recuperative power. In one patient the extraction of teeth and the short period of drainage which follows is sufficient to swing down the balance towards a recovery which may be permanent. In others a temporary improvement is followed by the gradual reappearance of their troubles. It is difficult to tell beforehand how any one particular patient will respond to extractions, and there are a certain number in whom it is difficult to decide whether alveolectomy is called for or whether simple extractions will prove sufficient. We may divide all patients into three classes. In the first come patients with one or perhaps two apical abscesses or a granuloma, in whom the process is limited, and whose general condition is good. For these it may reasonably be expected that simple extractions are all that is required. Class 3 consists of those who have an obvious diffuse infection of one or both alveolar processes and who show signs of a severe degree of toxæmia in addition to joint or fibrositic trouble. These call for alveolectomy. In this third class also come the patients whose alveolar processes show residual infection after their teeth have been extracted. Class 2 is the one which affords considerable difficulty. There may or may not be a granuloma, but two or three teeth show a considerable degree of periodontitis with early changes in the bone. Possibly the premolars show periodontitis, while the molars show loss of definition of their apices and of the surrounding alveolar bone. I believe that all such cases should have the position laid clearly before them and be advised to have alveolectomy performed, especially when there is any degree of toxæmia. These are the patients who are likely to improve with simple extractions, but after a time they will relapse and slowly become worse than before, because infected bone has been left behind.

Clinical Condition of Patient the Deciding Factor.

The interpretation of dental radiograms is a matter of considerable difficulty, and the difficulty lies, not in deciding which teeth are diseased, but in determining which are healthy. In practically every set of dental radiograms there are appearances which can be interpreted as evidence of disease. For instance, there are few people who do not show some degree of periodontitis, especially round their premolar teeth. Hence it is not possible to decide from the radiographic appearances alone what procedure must be undertaken to bring about the cure of any case. Just as it is the general clinical examination which in the first instance brings the teeth under suspicion, so the final decision can only be made on the results of this examination. The signs and symptoms must be evaluated and an attempt made to determine the degree of resistance and recuperative power, especially taking into consideration the amount of lassitude, tiredness, and mental depression. The blood must be examined to find out the degree of anaemia and the proportion of polymorphonuclear leucocytes to lymphocytes. Bacteriological and serological examinations should be made. These results are collated, and in the light of this knowledge the radiograms are examined in order that the final decision can be made as to the extent of the mischief and the procedure required to eradicate it. This decision must ensure, first, that no innocent teeth are sacrificed; and, secondly, that no infected tissue is left behind to continue the disease. Whatever course is decided upon, vaccine therapy will be required after the mouth has been dealt with. Finally, an immunising course of vaccine administration must always precede any operative measures, for there are a number of cases on record in which fatal septicæmia or septic pneumonia has followed the extraction of a number of infected teeth. It is, moreover, a matter of regrettably common experience to meet with patients in whom an infective process, involving only one or two joints, has flared up and affected many or all of the remaining joints because they had not previously been protected by an immunising course. In arthritis and the allied conditions we are dealing with some of the most prevalent and crippling diseases which afflict mankind, and our measures, both diagnostic and curative, must be commensurate.

ABDOMINAL PAIN IN PREGNANCY.

By C. S. LANE-ROBERTS, M.S. LOND.,
F.R.C.S. ENG.,

OBSTETRIC SURGEON TO OUT PATIENTS, ROYAL NORTHERN AND
QUEEN CHARLOTTE'S HOSPITALS.

MANY cases of abdominal pain in pregnancy, pain that is often severe and that occurs continuously or in crises, show no physical signs of any kind. Some people are undoubtedly sensitive to the stretching of the uterus and abdominal wall and to uterine contractions, but to the majority these gradual processes, with the incessant foetal movements, do not cause more than discomfort. Many women call for support of the pregnant abdomen, others cannot put up with any pressure on the skin. Parous women, however, generally need some form of corset or belt. Constipation and flatulence are almost universal during pregnancy and frequently give rise to pain. The stretching of the round ligaments often causes pain between the twelfth and thirtieth weeks either in the groins or in one or both sides of the uterus. During the early weeks the pain may cause suspicion of an extra-uterine gestation, appendicitis, or other serious lesion, but there may be no physical signs to support the diagnosis. Later on the pain is often in one or other hypochondrium or above Poupart's ligament, and may be severe enough to keep the patient in bed. There are, however, no physical signs, no tenderness, no rigidity, and no constitutional signs or symptoms.

The commoner organic causes of abdominal pain in pregnancy are as a rule easily recognised, though sometimes the differential diagnosis may be difficult. They may be considered in three groups: where the pain (1) appears limited to the uterus, (2) originates in the adnexa, and (3) is due to associated conditions.

Some Conditions Confined to the Uterus.

(a) *Undue stretching of the uterus*, in cases of dual pregnancy sometimes, in acute hydramnios always, gives rise to pain, breathlessness, and palpitation. The sudden increase of amniotic fluid in acute hydramnios is simple to diagnose, as it is rare, develops suddenly, and may be associated with albuminuria and other toxæmic signs. The symptoms are due less to the quantity of fluid than to the suddenness of its collection. The patient, as she lies propped up in bed, often looks like a cardiac case, with cyanosed lips and face. There may be flatulent dyspepsia, vomiting, constipation, a rapid pulse, and oedema of the legs, vulva, and lower abdomen, which is as tense as a drum and very tender. A fine thrill may be obtained, no foetal parts can be detected, but ballottement may usually be elicited by vaginal examination. Chronic or gradual hydramnios may be more difficult to diagnose from an ovarian cyst complicating pregnancy or an associated ascites. Some patients with ovarian tumours may give a history of amenorrhœa, while the breasts may be enlarged and secrete fluid, and the colour of the vagina may be bluer than usual from pressure. In such cases chief reliance should be placed on the general contour of the swelling, the fluid thrill, and the absence of foetal parts. The ovarian cyst complicating pregnancy may give considerable trouble in diagnosis, but ascites should not, although it may coexist with hydramnios.

(b) *Fibromyomata* are more common in pregnant women than is usually thought, a fact which proves that they often cause no symptoms. Those that give the trouble usually fall into one of three groups: (1) the subperitoneal pedunculated fibroids that may give rise to various mechanical changes, so causing pain; (2) the uterus distorted with fibroids, of which one is large and causes pressure symptoms; and (3) one of fibroid only, which is either very big or else of moderate size undergoing degeneration. Pain with fibroids is generally due to pressure from incarceration

or to secondary changes. The symptoms and signs of the former condition are usually pelvic pain, sciatica, pains down the legs; interference with bladder function, either frequency or—less commonly—retention of urine; and pressure on the veins, causing varicose veins, hæmorrhoids, and œdema of the legs. The so-called "red" degeneration is the commonest type; small cysts form in the tumour and venous thrombosis occurs. Clinically the onset is sudden, characterised by intense pain and tenderness over the tumour. If the fibroid is large there are marked constitutional signs—high temperature, rapid pulse, prostration, and severe constipation. The diagnosis is established by sudden tenderness in a fibroid which had been previously known as a painless tumour. There is no added liability to abortion. Rest in bed usually brings about an alleviation of symptoms which seldom last for more than a few days. Operation is rarely called for and should be avoided if possible, as these fibroids are usually deep-seated and a myomectomy much increases the chances of abortion.

(c) Pain may be very prominent in *concealed accidental hæmorrhage*, which usually occurs in multigravida between the thirty-fourth and thirty-eighth week, and may become one of the most serious catastrophes of pregnancy. The mildest cases should be fully investigated at the onset of the first hæmorrhage. In a typically severe case the patient may feel off colour for a day or so; then, perhaps during some exertion, she suddenly feels severe abdominal pain. This may be described as "something giving way," a "bursting" sensation, or as if some "tight band" of constriction were being tied round the abdomen. It may be indescribably bad, with no alleviation at all, so that the patient rolls about in agony and may faint or vomit.

All degrees of concealed hæmorrhage occur; some accompany or follow a revealed hæmorrhage, and in others the external hæmorrhage appears later. All cases need immediate treatment and very careful nursing and watching.

(d) A *hydatidiform mole*, when it causes sudden stretching of the uterus, may cause great pain, which is apt to be most severe when hæmorrhage has occurred in some of the attachments of the mole to the uterine wall. These cases as a rule closely simulate a concealed hæmorrhage, for in both the uterus is of a hard, board-like consistency and markedly tender, and no foetal parts can be felt or foetal heart heard. Hydatidiform moles usually occur in the earlier months of pregnancy, when the differential diagnosis is not so difficult.

(e) *Rupture of the uterus in pregnancy* is rare, but about 4 per cent. of Cesarean section scars rupture, so that old Cesarean cases need watching when there is any unusual abdominal pain before or at term. The rupture may be partial or complete, and is usually ushered in by abdominal pain or vomiting. The pain may be very severe if there is intraperitoneal bleeding or spilling of liquor amnii. Shock is usually due to the onset of labour. The temperature becomes subnormal, the pulse rapid, running, and feeble, accompanied by cold sweating, vomiting, and pallor. On examination the abdomen is found to contain free fluid, and the fœtus may be free in the peritoneal cavity. Surgical attention should not be delayed. If the placenta is attached to the scar there may be very little pain, but a fatal hæmorrhage may occur in a very short time.

Spontaneous rupture of the uterus may occur in a pregnancy in one horn of a bicornate uterus, the accident being analogous to the rupture of the tube in a tubal gestation. Rare cases have been reported of the spontaneous rupture of the uterus during the later months for no apparent reason; they are said to be due to some weakness of the uterine musculature. These cases are associated with marked abdominal pain and shock due to the escape of liquor amnii and blood into the peritoneal cavity. Although rupture of the uterus in pregnancy is a very serious accident it is not attended by the same degree of shock and danger as is rupture of the uterus during labour. If,

however, the rupture is of a cornual or an interstitial pregnancy the hæmorrhage may prove fatal in a few minutes.

Traumatic rupture of the uterus is always the result of direct violence, and there is much shock due to pain and hæmorrhage.

Pain Originating in the Adnexa.

The commonest cause of this is probably rupture of an extra-uterine pregnancy. The pain is usually very sudden; the patient may be able to say exactly what she was doing when it started, and it is so severe as to double her up. Often it is accompanied by faintness and sickness, due either to the severity of the pain or the degree of intraperitoneal bleeding or to both. The patient then rests, and either the pain is alleviated or the subsequent getting-up causes a return. The pain of rupture with an extensive intraperitoneal hæmorrhage may be very severe, with marked abdominal tenderness; these are usually the cases with a general effusion of blood. The pain of a tubal mole or slowly leaking erosion may be trifling, and no worse than a mild colic.

Salpingitis or salpingo-oöphoritis rarely lights up in pregnancy.

If ovarian tumours cause pain they usually do so either from pressure or from some axial rotation or degeneration. Rupture of the cyst may occur after incarceration, infection from the bowel with acute abdominal symptoms, or hæmorrhage. In most cases surgical treatment is called for, and is certainly indicated when there is abdominal pain and tenderness. The pain may be due to free blood in the peritoneal cavity, which may come from (a) rupture of a tubal or ovarian pregnancy; (b) an interstitial pregnancy or rupture of a cornual pregnancy in a bicornate uterus; (c) rupture of a uterine scar, from Cesarean section or myomectomy; (d) rupture of a uterine vein. All these are severe cases, owing to the amount of blood lost, and in some the hæmorrhage may very quickly prove fatal. Ruptured tubal pregnancy is by far the commonest.

Rare though they are, the secondary abdominal and broad-ligament pregnancies must not be forgotten, as they may prove formidable problems at operation. Living full-term children have been removed from an amniotic sac that has grown either free in the abdomen or between the layers of the broad ligament.

Epigastric pain is an important prodromal symptom in pre-eclamptic toxæmia. Various explanations have been suggested to account for this pain, which may be very severe. The suggestion that in the worst cases it may be due to stretching of the peritoneum and capsule of the liver by the subcapsular hæmorrhage may be correct occasionally. Epigastric pain may come on shortly before an eclamptic fit, and may be the only prodromal symptom. Other upper abdominal pains occur in heart cases where compensation is failing and in tabetics, although severe abdominal crises are seldom seen outside infirmary practice.

Associated Conditions.

(1) *Pyelitis of pregnancy* is very frequent. Clinically the cases can usually be grouped under one of the following types.

(a) The renal type—where the signs and symptoms point to one or other kidney. There is severe pain in the back and loin, or on one side, more often the right. The patient feels and looks ill and has a furred tongue and often a shivering attack and rise of temperature. Headache is usually severe, but urinary symptoms are seldom complained of. The muscles over the painful area are rigid and the kidney is definitely tender. This is the type of case that will improve in a few days with rest in bed and the usual careful treatment, but is very liable to relapse with a recrudescence of all the symptoms. Sometimes the case is more severe with excruciating pain in the right iliac fossa and loin and marked tenderness and rigidity, ushered in by rigors and often accompanied by a temperature of 103° or 104° F. and a very rapid pulse-rate. Once treatment has been established the condition improves, but

recuperative power. In one patient the extraction of teeth and the short period of drainage which follows is sufficient to swing down the balance towards a recovery which may be permanent. In others a temporary improvement is followed by the gradual reappearance of their troubles. It is difficult to tell beforehand how any one particular patient will respond to extractions, and there are a certain number in whom it is difficult to decide whether alveolectomy is called for or whether simple extractions will prove sufficient. We may divide all patients into three classes. In the first come patients with one or perhaps two apical abscesses or a granuloma, in whom the process is limited, and whose general condition is good. For these it may reasonably be expected that simple extractions are all that is required. Class 3 consists of those who have an obvious diffuse infection of one or both alveolar processes and who show signs of a severe degree of toxæmia in addition to joint or fibrositic trouble. These call for alveolectomy. In this third class also come the patients whose alveolar processes show residual infection after their teeth have been extracted. Class 2 is the one which affords considerable difficulty. There may or may not be a granuloma, but two or three teeth show a considerable degree of periodontitis with early changes in the bone. Possibly the premolars show periodontitis, while the molars show loss of definition of their apices and of the surrounding alveolar bone. I believe that all such cases should have the position laid clearly before them and be advised to have alveolectomy performed, especially when there is any degree of toxæmia. These are the patients who are likely to improve with simple extractions, but after a time they will relapse and slowly become worse than before, because infected bone has been left behind.

Clinical Condition of Patient the Deciding Factor.

The interpretation of dental radiograms is a matter of considerable difficulty, and the difficulty lies, not in deciding which teeth are diseased, but in determining which are healthy. In practically every set of dental radiograms there are appearances which can be interpreted as evidence of disease. For instance, there are few people who do not show some degree of periodontitis, especially round their premolar teeth. Hence it is not possible to decide from the radiographic appearances alone what procedure must be undertaken to bring about the cure of any case. Just as it is the general clinical examination which in the first instance brings the teeth under suspicion, so the final decision can only be made on the results of this examination. The signs and symptoms must be evaluated and an attempt made to determine the degree of resistance and recuperative power, especially taking into consideration the amount of lassitude, tiredness, and mental depression. The blood must be examined to find out the degree of anæmia and the proportion of polymorphonuclear leucocytes to lymphocytes. Bacteriological and serological examinations should be made. These results are collated, and in the light of this knowledge the radiograms are examined in order that the final decision can be made as to the extent of the mischief and the procedure required to eradicate it. This decision must ensure, first, that no innocent teeth are sacrificed; and, secondly, that no infected tissue is left behind to continue the disease. Whatever course is decided upon, vaccine therapy will be required after the mouth has been dealt with. Finally, an immunising course of vaccine administration must always precede any operative measures, for there are a number of cases on record in which fatal septicæmia or septic pneumonia has followed the extraction of a number of infected teeth. It is, moreover, a matter of regrettably common experience to meet with patients in whom an infective process, involving only one or two joints, has flared up and affected many or all of the remaining joints because they had not previously been protected by an immunising course. In arthritis and the allied conditions we are dealing with some of the most prevalent and crippling diseases which afflict mankind, and our measures, both diagnostic and curative, must be commensurate.

ABDOMINAL PAIN IN PREGNANCY.

By C. S. LANE-ROBERTS, M.S. LOND.,
F.R.C.S. ENG.,

OBSTETRIC SURGEON TO OUT PATIENTS, ROYAL NORTHERN AND
QUEEN CHARLOTTE'S HOSPITALS.

MANY cases of abdominal pain in pregnancy, pain that is often severe and that occurs continuously or in crises, show no physical signs of any kind. Some people are undoubtedly sensitive to the stretching of the uterus and abdominal wall and to uterine contractions, but to the majority these gradual processes, with the incessant foetal movements, do not cause more than discomfort. Many women call for support of the pregnant abdomen, others cannot put up with any pressure on the skin. Parous women, however, generally need some form of corset or belt. Constipation and flatulence are almost universal during pregnancy and frequently give rise to pain. The stretching of the round ligaments often causes pain between the twelfth and thirtieth weeks either in the groins or in one or both sides of the uterus. During the early weeks the pain may cause suspicion of an extra-uterine gestation, appendicitis, or other serious lesion, but there may be no physical signs to support the diagnosis. Later on the pain is often in one or other hypochondrium or above Poupart's ligament, and may be severe enough to keep the patient in bed. There are, however, no physical signs, no tenderness, no rigidity, and no constitutional signs or symptoms.

The commoner organic causes of abdominal pain in pregnancy are as a rule easily recognised, though sometimes the differential diagnosis may be difficult. They may be considered in three groups: where the pain (1) appears limited to the uterus, (2) originates in the adnexa, and (3) is due to associated conditions.

Some Conditions Confined to the Uterus.

(a) *Undue stretching of the uterus*, in cases of dual pregnancy sometimes, in acute hydramnios always, gives rise to pain, breathlessness, and palpitation. The sudden increase of amniotic fluid in acute hydramnios is simple to diagnose, as it is rare, develops suddenly, and may be associated with albuminuria and other toxæmic signs. The symptoms are due less to the quantity of fluid than to the suddenness of its collection. The patient, as she lies propped up in bed, often looks like a cardiac case, with cyanosed lips and face. There may be flatulent dyspepsia, vomiting, constipation, a rapid pulse, and œdema of the legs, vulva, and lower abdomen, which is as tense as a drum and very tender. A fine thrill may be obtained, no foetal parts can be detected, but ballottement may usually be elicited by vaginal examination. Chronic or gradual hydramnios may be more difficult to diagnose from an ovarian cyst complicating pregnancy or an associated ascites. Some patients with ovarian tumours may give a history of amenorrhœa, while the breasts may be enlarged and secrete fluid, and the colour of the vagina may be bluer than usual from pressure. In such cases chief reliance should be placed on the general contour of the swelling, the fluid thrill, and the absence of foetal parts. The ovarian cyst complicating pregnancy may give considerable trouble in diagnosis, but ascites should not, although it may coexist with hydramnios.

(b) *Fibromyomata* are more common in pregnant women than is usually thought, a fact which proves that they often cause no symptoms. Those that give trouble usually fall into one of three groups: (1) the subperitoneal pedunculated fibroids that may give rise to various mechanical changes, so causing pain; (2) the uterus distorted with fibroids, of which one is large and causes pressure symptoms; and (3) one of fibroid only, which is either very big or else of moderate size undergoing degeneration. Pain with fibroids is generally due to pressure from incarceration

As aids to the non-touch technique the following instruments will be found useful. Most of them come under the category of "combined instruments." For suturing wounds the surgeon can have nothing better than a Lane's dissecting forceps in the left hand and scissors of the Patiala pattern in the right.

FIG. 2.

Forceps and knife combined.

With the tenaculum points of a Lane's forceps tissues can be picked up and adjusted to a nicety, and with its serrated surfaces well in contact ligatures or needles may be securely held. The original pattern of Patiala scissors is not quite suitable, but

FIG. 3.

Scissors and forceps combined.

Gillies's or my modification (Fig. 1) suit the requirements well. It is a needle-holder and scissors combined, and the surgeon who once gets used to it will not be likely to give it up.

The instrument best adapted to an assistant is one that combines the properties of a forceps

and a cutting instrument. I have devised two types.

1. *A forceps and knife combined*, in which a Bard-Parker or other removable blade is slipped on to a special device at the end of a Lane's dissecting forceps (Fig. 2). It should be held with the edge of the knife looking in the direction of the finger-tips. The blade should not be pointed.

2. *A scissors and forceps combined*, in which the forceps are made as an extension of the bows (Fig. 3). It should be held with the fingers in the loops, but

FIG. 4.

Selvaduria's ligature holder.

more in the manner of forceps than scissors, and with the convex surface towards the palm, so that the forceps ends project out. When thus held the same grip ensures its easy use either as scissors or forceps. With either of these two instruments an assistant can pick up a mop for swabbing, adjust wound edges, hold a running ligature taut, or cut a ligature. Of the two, the second is much the more serviceable and satisfactory.

For threading needles of the Reverdin type, such as the modification of Wu and Bonney, a useful instrument is the U-shaped forceps designed by my former house surgeon, Mr. David Selvaduria (Fig. 4).

Messrs. Down Bros., London, S.E., are the makers of all these instruments.

A CASE OF

HUMAN INFESTATION WITH LIVER FLUKE.

By S. W. PATTERSON, M.D. MELB., D.Sc.,
M.R.C.P. LOND.,

PHYSICIAN AND BACTERIOLOGIST, RUTHIN CASTLE,
NORTH WALES.

IN man the liver fluke (*Fasciola hepatica*) is a rare parasite, only 28 cases of infestation having been recorded in the literature up to 1915.¹ The early cases were discovered at autopsy; the first described being by Pallas in 1760 in a female in Berlin. The infection was mostly mild, and no symptoms or only trifling ones were present. In other cases a severe infection may lead to death; the symptoms, enlargement and painfulness of the liver, merely pointed to a disease of the liver. Of the 16 cases reported up to 1902 (Duffek²), jaundice occurred in three only.

In the present case the patient was a man, aged 43, who had been for nine months in West Africa in 1912, but had had no illness then or at other times except scarlet fever in 1910, influenza in 1918, and a pneumococcal septicæmia following infection at operation in 1921. The illness started at the beginning of November, 1927, with chills and mild rigors; the temperature, normal in the morning, would rise to 102°-103° at night followed by sweating. In addition to general malaise, there was an uncomfortable feeling in the upper abdomen, not related to food, and an irritating spasmodic cough which sometimes brought on vomiting. The patient went to a nursing home in Liverpool, where no abnormality was found except a leucocytosis of 18,000 per c.mm. with 11,000 (62 per cent.) eosinophil cells. The fever subsided, but discomfort in the abdomen continued, and at times severe attacks of colic occurred. There was no jaundice.

When seen at the beginning of January of this year ordinary physical examination revealed nothing abnormal; but the blood showed a leucocytosis of 11,700, of which 6200 (53 per cent.) were eosinophils. X ray examination was negative, except that the gall-bladder was not normally filled after the administration of iodoquin, and the faint shadow obtained appeared mottled. The watery stools after Epsom salts contained numerous ova of *F. hepatica*. The treatment adopted was non-surgical biliary drainage by drachm doses of 50 per cent. magnesium sulphate twice a week on an empty stomach, increasing doses of hexamine

with bicarbonate of soda, and intravenous injections of stibosan, a preparation of tartar emetic.

The abdominal symptoms disappeared and the patient is well; the blood, however, shows still moderate eosinophilia, and ova are found in the stools when concentrating methods are used (see table).

Aug. 8 ..	8,000		4	320	..

The following points are of interest in the case:—

1. *Diagnosis*.—As has been said, the diagnosis was made at autopsy in the early cases described. The ova can be found in the faeces, as in Ward's case³; but adult flukes would probably be digested during their passage through the alimentary canal. Clark⁴ has found flukes in the pus at operation on empyema of the gall-bladder. Complement fixation has been described in liver fluke infections in sheep,⁵ but as far as I know has not been applied in man. In the present case the symptoms pointed to cholecystitis with colic; the abnormal condition of the gall-bladder and the eosinophilia were explained by finding the characteristic ova, which are oval in shape, 140-160 μ long and 80 μ broad.

2. The high degree of *eosinophilia*. This is found in worm infections, especially during the invasion stage. In Ward's case³ the eosinophils were 3700-6000 per c.mm., and up to 41 per cent. of the total leucocytes. Lawton⁶ in Egypt found an *eosinophilia* in some cases of pyrexia of unknown origin (P.U.O.), which when traced afterwards were shown to be

much more slowly, so that the patient may be thoroughly debilitated for the rest of her pregnancy. She may have sudden exacerbations of symptoms without any apparent cause, and relapsing attacks in the puerperium.

(b) The abdominal type, where the abdominal pain is so severe that there may be difficulty in deciding whether the case is not one of appendicitis, cholecystitis, or intestinal obstruction. There is abdominal distension, rigidity, nausea, and perhaps vomiting with constipation. The temperature may rise to 103° or 104° and the pain may be excruciating. The patient may take a long time to improve and be very enfeebled for the rest of her pregnancy.

(c) The generalised type, where there is not much abdominal pain and the signs and symptoms are not localised to the abdomen. This group will not be considered here; the prognosis is bad for both mother and foetus.

(2) *Acute Appendicitis*.—Pregnancy does not predispose to appendicitis, but the growing uterus may pull on and disturb adhesions formed after a previous attack, and may thus excite a renewal of the disease. It may be very difficult to diagnose, and in all suspect cases a careful examination of the urine and the blood should be made. The enlarged uterus, it should be noted, tends to raise the cæcum and appendix in the later months higher in the abdomen than normal. Almost 80 per cent. of the cases occur in the earlier months; they are rare in labour, and only occasionally come on in the puerperium. The mortality-rate is high, especially when there is suppuration; in one series of 500 cases over 30 per cent. proved fatal, and the incidence of foetal death and abortion was 40 per cent. Pregnancy aggravates chronic appendicular infection, especially when the appendix is abnormal in length, mobility, shape, or position. Gangrene and perforation occur more rapidly during pregnancy. According to Lee there is more violent and widespread peritonitis, a weaker reaction, less likelihood of protective adhesions, increased vascularity, greater danger of thrombosis and embolism, less adequate drainage, more frequent abscess formation, and earlier intestinal obstruction. The mortality, which is higher after the seventh month, may be called the "mortality of delay." Where there is uncertainty a blood count should be done promptly; a leucocytosis of over 12,000 may be said to indicate surgical interference. Up to the fourth month the signs are as easily recognisable as in the non-pregnant. A rise of temperature, with vomiting, constipation, and localised and well-marked rigidity in the appendicular region, will usually point to the source of the trouble. The sudden onset, rapid pulse, and rise of temperature should distinguish the vomiting from that of pregnancy. The later cases, after perforation has occurred, always need operative treatment. Some cases of suppurative peritonitis may be difficult to distinguish from a concealed accidental hæmorrhage, but—although there is generalised abdominal pain and rigidity—there is in peritonitis a maximum of tenderness in the areas not occupied by the uterus, the flanks, and epigastrium.

(3) *Intestinal obstruction* may be difficult to diagnose in pregnancy. The "pernicious" vomiting of pregnancy begins early and steadily gets worse; its onset is rarely acute, it is not associated with pain, distension of the intestines, or interference with the passage of flatus, and it may be relieved by rectal feeding. Analysis of the urine should help the decision. Treatment is always surgical, if possible without disturbing the pregnancy. The intestinal obstruction may be due to the pregnancy, as in adhesions, a fibroid or ovarian neoplasm, or even the pressure of the pregnant uterus. Or it may be due to a separate and associated condition, such as a strangulated hernia, a volvulus, or a pelvic abscess.

(4) *Retroverted uterus*, with retention of urine, is important between the twelfth and sixteenth weeks of pregnancy. So many women in a normal pregnancy have backache and frequency of micturition at this stage that the condition of overflow incontinence resulting from incarceration of the retroverted pregnant

uterus may be missed. There is great abdominal pain and acute distress. With the onset of cystitis the temperature and pulse rise and the patient is acutely ill. In spite of the characteristic physical signs a retroverted gravid uterus may easily be mistaken for other conditions of serious import—e.g., an intrapelvic ovarian cyst, some other tumour, a hæmatocele from a ruptured tubal pregnancy, or a retro-uterine fibroid with pregnancy.

(5) *Gall-bladder pain* occurs sometimes, more often in the later weeks of pregnancy, and calls for dietetic measures and medical treatment. Acute cholecystitis is rare, but the pain, which starts in the right epigastrium and hypochondrium, generally radiates to the right shoulder. Unless operated on at an early stage the gall-bladder is likely to rupture and cause a severe form of suppurative peritonitis.

(6) *Acute pneumonia* may show itself by acute abdominal pain and rigidity in the early stages, and may easily be missed.

(7) *Calculi*, renal, ureteric, and vesical, do occur in pregnancy, and may cause acute abdominal pain and need surgical treatment.

(8) *Suppurative pelvic peritonitis* may arise from many cases—e.g., appendicitis, acute cholecystitis, perforation of the pouch of Douglas by an instrument, and rupture of a pelvic abscess or a pyosalpinx.

Clinical and Laboratory Notes.

A NOTE ON

SOME INSTRUMENTS USEFUL IN THE NON-TOUCH TECHNIQUE OF SURGERY.

BY R. L. SPITTEL, F.R.C.S. ENG.,
SURGEON, GENERAL HOSPITAL, COLOMBO.

THE tendency of modern surgery is to discourage anything suggestive of unnecessary handling of tissues. The ideal set by bone and joint surgery, where even the gloved hand never once comes in contact with the wound, may be impracticable in certain other regions, such as the abdomen. This, however, is no reason why, once the necessary manipulations have been completed, the rest of the operation should not be conducted on the same high plane as the orthopaedic operation. The omentum and peritoneum undoubtedly atone for many surgical delinquencies, and it is a significant truism—that a

FIG. 1.

Modified Patlak self-scorer.

good abdominal surgeon is sometimes a poor orthopaedist. Whenever possible, neither the gloved hand nor anything that comes in contact with it (such as swabs, ligatures, needles, or the working ends of instruments) should be permitted to touch the open wound. This is perhaps a counsel of perfection, but we need not fall far short of it—and that without sacrificing much time—if we cultivate the habit with the ideal in view. With a little practice it is quite easy to acquire the art of mopping, sewing, and ligating entirely with forceps. Incidentally, the economy in ligature material will be considerable, for no less than six knots may easily be tied with forceps with a length that will only allow one to be tied with the hand.

As aids to the non-touch technique the following instruments will be found useful. Most of them come under the category of "combined instruments." For suturing wounds the surgeon can have nothing better than a Lane's dissecting forceps in the left hand and scissors of the Patiala pattern in the right.

Forceps and knife combined.

With the tenaculum points of a Lane's forceps tissues can be picked up and adjusted to a nicety, and with its serrated surfaces well in contact ligatures or needles may be securely held. The original pattern of Patiala scissors is not quite suitable, but

Scissors and forceps combined.

Gillies's or my modification (Fig. 1) suit the requirements well. It is a needle-holder and scissors combined, and the surgeon who once gets used to it will not be likely to give it up.

The instrument best adapted to an assistant is one that combines the properties of a forceps

and a cutting instrument. I have devised two types.

1. *A forceps and knife combined*, in which a Bard-Parker or other removable blade is slipped on to a special device at the end of a Lane's dissecting forceps (Fig. 2). It should be held with the edge of the knife looking in the direction of the finger-tips. The blade should not be pointed.

2. *A scissors and forceps combined*, in which the forceps are made as an extension of the bows (Fig. 3). It should be held with the fingers in the loops, but

Selvaduria's ligature holder.

more in the manner of forceps than scissors, and with the convex surface towards the palm, so that the forceps ends project out. When thus held the same grip ensures its easy use either as scissors or forceps. With either of these two instruments an assistant can pick up a mop for swabbing, adjust wound edges, hold a running ligature taut, or cut a ligature. Of the two, the second is much the more serviceable and satisfactory.

For threading needles of the Reverdin type, such as the modification of Wu and Bonney, a useful instrument is the U-shaped forceps designed by my former house surgeon, Mr. David Selvaduria (Fig. 4).

Messrs. Down Bros., London, S.E., are the makers of all these instruments.

A CASE OF HUMAN INFESTATION WITH LIVER FLUKE.

By S. W. PATTERSON, M.D. MELB., D.Sc.,
M.R.C.P. LOND.,

PHYSICIAN AND BACTERIOLOGIST, RUTHIN CASTLE,
NORTH WALES.

IN man the liver fluke (*Fasciola hepatica*) is a rare parasite, only 28 cases of infestation having been recorded in the literature up to 1915.¹ The early cases were discovered at autopsy; the first described being by Pallas in 1760 in a female in Berlin. The infection was mostly mild, and no symptoms or only trifling ones were present. In other cases a severe infection may lead to death; the symptoms, enlargement and painfulness of the liver, merely pointed to a disease of the liver. Of the 16 cases reported up to 1902 (Duffek²), jaundice occurred in three only.

In the present case the patient was a man, aged 43, who had been for nine months in West Africa in 1912, but had had no illness then or at other times except scarlet fever in 1910, influenza in 1918, and a pneumococcal septicæmia following infection at operation in 1924. The illness started at the beginning of November, 1927, with chills and mild rigors; the temperature, normal in the morning, would rise to 102°-103° at night followed by sweating. In addition to general malaise, there was an uncomfortable feeling in the upper abdomen, not related to food, and an irritating spasmodic cough which sometimes brought on vomiting. The patient went to a nursing home in Liverpool, where no abnormality was found except a leucocytosis of 15,000 per c.mm., with 11,000 (62 per cent.) eosinophil cells. The fever subsided, but discomfort in the abdomen continued, and at times severe attacks of colic occurred. There was no jaundice.

When seen at the beginning of January of this year ordinary physical examination revealed nothing abnormal; but the blood showed a leucocytosis of 14,700, of which 6200 (42 per cent.) were eosinophils. X-ray examination was negative, except that the gall-bladder was not normally filled after the administration of iodolikon, and the faint shadow obtained appeared mottled. The watery stools after Epsom salts contained numerous ova of *F. hepatica*. The treatment adopted was non-surgical biliary drainage by drachm doses of 50 per cent. magnesium sulphate twice a week on an empty stomach, increasing doses of hexamine

with bicarbonate of soda, and intravenous injections of stibosan, a preparation of tartar emetic.

The abdominal symptoms disappeared and the patient is well: the blood, however, shows still moderate eosinophilia, and ova are found in the stools when concentrating methods are used (see table).

Date.	Total leucocytes.	Eosinophils.		Ova in stools.

" 16	8,800	7	600	+
Aug. 8	8,000	4	320	..

The following points are of interest in the case:—

1. *Diagnosis.*—As has been said, the diagnosis was made at autopsy in the early cases described. The ova can be found in the faeces, as in Ward's case³; but adult flukes would probably be digested during their passage through the alimentary canal. Clark⁴ has found flukes in the pus at operation on empyema of the gall-bladder. Complement fixation has been described in liver fluke infections in sheep,⁵ but as far as I know has not been applied in man. In the present case the symptoms pointed to cholecystitis with colic; the abnormal condition of the gall-bladder and the eosinophilia were explained by finding the characteristic ova, which are oval in shape, 140-160 μ long and 80 μ broad.

2. The high degree of *eosinophilia*. This is found in worm infections, especially during the invasion stage. In Ward's case³ the eosinophils were 3700-6000 per c.mm., and up to 41 per cent. of the total leucocytes. Lawton⁶ in Egypt found an eosinophilia in some cases of pyrexia of unknown origin (P.U.O.), which when traced afterwards were shown to be

infected with bilharzia. Dévé⁷ and later Dew⁸ found a marked eosinophilic reaction of the endothelial cells and leucocytes round the growing hydatid cyst in the livers of artificially infected pigs.

3. The mode of infection is usually by impure water or infected uncooked vegetables, such as watercress. In Duffek's case,² as in the present one, the infection began in October or the beginning of November, and the summer of 1901 like that of 1927 had been very wet and liver fluke had been a common disease of the sheep in the districts in which the cases occurred. As early as the fourteenth century the disease in sheep was described by Jehan de Brie⁹ in his book on "the whole art of shepherding," "Traicté de l'estat, science et pratique de l'art de Bergerie, et de garder oïlles et brebis à laine," published in 1379, and presented to the learned King Charles V. Chapter xxviii. of this book deals with "Dauve, a small herb (*Ranunculus lingua* and *R. flammula*) which by corruption when eaten engenders a sort of worm, which gets into and destroys the liver. Therefore the shepherd must keep his sheep away from marshes and low pastures in the month of March." It is now known that the infection is carried by water and uncooked vegetables, and that the pond snails (*Limnaea*) act as intermediate hosts.

A CASE OF RUPTURE OF THE OESOPHAGUS BY INDIRECT VIOLENCE.

By J. R. MURDOCH, M.B. EDIN.,

FIRST ASSISTANT MEDICAL OFFICER, NORTH MIDDLESEX
HOSPITAL, N.

THE following case of rupture of the oesophagus seems worthy of record:—

A boy, aged 6 years, was admitted to the North Middlesex Hospital after having been knocked down and run over by a motor-cycle. When seen on admission he was quite unconscious, with hæmorrhage from the nose and mouth. He died a few hours after admission.

Post-mortem examination revealed marked bruising of left chest wall and over left hip-joint, extensive bruising of scalp on left side, and a comminuted fracture of left humerus. The heart, larynx, and trachea were normal. Left pleural cavity was partially filled with dark reddish-brown fluid containing small particles of food. The base of the left lung was collapsed and very congested. No ribs were fractured, and the right pleural cavity and lung were normal.

A longitudinal tear was found on the left side of the oesophagus $\frac{1}{2}$ in. above diaphragm and $1\frac{1}{2}$ in. long. There was also a slight rupture of the diaphragm around the oesophageal opening. The oesophageal wall was extremely thin. The abdominal organs were all normal with no signs of injury. A large fracture of the skull was found running from the vault on the left side down into the left middle fossa, and there was an extensive extradural hæmorrhage on the left side.

It would appear from the examination of this case that the motor-cycle wheel passed over the boy's chest and in this way stretched the diaphragm around the oesophageal opening, with the resulting rupture of the diaphragm and the oesophagus above it. A few cases of spontaneous rupture of the oesophagus have been recorded and usually the tear has been longitudinal, but very few cases of rupture by indirect violence can be found in the literature. In this case the oesophageal wall was extremely thin, but showed no evidence of gross disease in any part.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF TROPICAL DISEASES.

At a meeting of this Section held on Dec. 6th Dr. J. G. THOMSON took the chair, and a discussion on

CLINICAL AND PATHOLOGICAL CORRELATION IN TYPHOID AND ALLIED DISEASES

was opened by Dr. H. H. SCOTT, who illustrated his points by relating cases from his own experience. Typhoid, he said, was such a protean disease that the typical symptoms might be either in abeyance or so overshadowed by some symptom or syndrome that the true nature of the malady might escape the doctor. Sometimes these anomalies might be accounted for in the post-mortem room. The first anomalous group was that marked by unusual modes of onset or in which some prominent symptom led the observer off the scent. He gave three examples of this: (1) *Onset with a chill*. He had seen a white woman of 27, eight months pregnant, who had got up quite well in the morning and had a shivering fit at 10 A.M. which had lasted for an hour. At the end of it labour had begun and a healthy infant had been born. The mother had then gone on to typical typhoid fever. In another case—which would also serve as an example of pneumotyphoid—a native boy of 19 had been ill for several days before he saw the doctor, and by that time he had all the signs of lobar pneumonia. Consolidation had been found post mortem, but so also had typhoid ulcers. (2) *Signs of peritonitis*. A native of 20 had died with the signs of general peritonitis. At autopsy the peritonitis was found to be the result of perforation of a typhoid ulcer. The lad had apparently felt no serious discomfort before the perforation. (3) *Ambulatory Forms*. There was no doubt that the man who kept about in the early stages of typhoid was running a very grave risk; the mortality-rate was largely kept up by these cases. Dr. Scott illustrated this type from his own attack of typhoid. After ten days of severe headache and rising temperature he had examined the agglutination of his serum, but it had been negative, and was again negative five days later. On the seventeenth day of the illness, with a temperature of 103.6° F., he had had to travel several miles to give evidence in court, and had gone to bed on his return. So severe had the attack been that the temperature was not normal until the sixty-third day. The blood had given no reaction until the second relapse on the forty-eighth day.

The second group of anomalous cases was that in which special symptoms or unusual complications appeared. The first type was the nervous one. True meningitis might occur, more often serous than suppurative. He had seen a hemiplegic negro in whom the brain had been found normal post mortem, but typhoid ulceration had been present in the intestine. A Canadian man had developed local neuritis of both legs in his third attack of typhoid—a very severe one with two relapses, three severe hæmorrhages, and a temperature of 105°–106° for six days. He had had very tender toes and excruciating pain in the calves and feet. Two years later there was still abnormal fatigability and numbness. The second type was when peculiar forms of fever occurred. He had seen three afebrile cases, all exceptionally severe, and inverse and intermittent fever. Anomalous temperature charts might be the result of multiplication of the bacillus in the meninges, the kidney, or the biliary system. The third was masking of the basal condition by coincident disease. Typhoid might occur in a tuberculous patient or might localise early in the lungs, and tuberculosis might simulate typhoid. In malarial subjects the advent of typhoid might be preceded by paroxysms indistinguishable from ague, except that quinine did not check them. Any disease supervening on malaria was apt to assume an inter-

mittent or periodic character. Typhoid and malaria might simulate each other. The coincidence of the two was an interesting example of the antagonism of diseases—a principle now used therapeutically in the malarial treatment of general paralysis. He showed temperature charts illustrating the extreme mildness of typhoid fever in malarial patients; the trouble had been to keep them in bed. Yet they had occurred in a country where both typhoid and malaria were very severe, had a high mortality, and—occurring alone—caused prolonged illness and marked debility.

Dr. H. B. DAY reviewed the course of the typhoid infection from the pathological point of view. Mallory, 30 years ago, had shown that the reaction of the host was due to a proliferation of the reticulo-endothelial system, so that there was an aggregation of macrophages in the lymph nodes and vessels. The first clinical symptoms were due to the increase of toxic products in the circulation at a rate greater than could be neutralised or eliminated. The clinical symptoms at the end of the first week were due to the reactions of the body to bacilli in various parts. The reticulo-endothelial cells succumbed, necrosed, and became immersed in fibrin.

Laboratory Tests.

The progressive leucopenia corresponded to the lack of attraction of the typhoid bacillus for polymorphonuclear leucocytes. Macrophages were not seen in an ordinary blood film, as they were ruptured. Urine tests were not sufficiently elective to be of much diagnostic value. Blood culture was usually positive in the first week, and might remain so up to the fourth week. It was the best means of positive diagnosis and there was no evidence that it failed in vaccinated persons. As only small numbers of bacilli got into the blood at any one time the results could not be uniformly successful; 80 per cent. was the highest success claimed. Stool and urine cultures were not conclusive, but could be tried later than blood culture. Carriers might cause a wrongful diagnosis, and on the other hand a genuine case might be missed, as the typhoid bacilli formed such a small proportion of the total flora of the stool. The Widal serum test was still the most convenient when a laboratory was not at hand, though it might be misleading in carriers and the recently vaccinated. Dudgeon had shown that fresh stimulation led to an increased yield of any antibody with which the body had previously been reacting—this was the principle of "protein shock," an unhappy term since the toxic antigen was certainly non-protein. The test might not be positive until late in the disease. The serum should be examined as early as possible, so as to be able to show a negative test turning positive. The agglutination reaction was the outward and visible sign of a chemical change. The typhoid antigen was readily absorbed by the blood elements and only freed by their disintegration. If the majority of it were soaked up by the macrophages the reaction might be negative.

Dr. P. MANSON-BAHR described his experience of work on typhoid in Gallipoli. It might not be possible to diagnose by the agglutination reaction a paratyphoid A infection until convalescence in a patient who had previously been inoculated against typhoid. During the war they had had to rely more and more on hæmoculture, although 80 per cent. of correct results was not often achieved. The urine test was very valuable in the second and third weeks, but he was less optimistic about faecal culture. Often these well-tried servants of clinical medicine failed when they were most expected to succeed, and the man who specialised in fevers must also be a clinical pathologist and must never neglect the evidence of his eye, his stethoscope, and his finger. Marris's test had rather fallen into disfavour, but was most useful if conducted with proper precautions, as laid down by Marris. Some of the typhoid-paratyphoid infections was dead in this country.

Clinical Features.

Dr. E. W. GOODALL said he was impressed by the uniformity of typhoid; wherever it was encountered

it was the same disease. He could parallel from his own experience every one of Dr. Scott's cases. Pneumonia headed the list of mistaken typhoid diagnoses in every fever hospital; it might be accompanied by diarrhoea, abdominal pain, and enlargement of the spleen. He urged the importance of more co-operation between clinician and pathologist. He had tried typhoid serum, typhoid toxin, and injections of dead bacilli therapeutically, and in each case had had a few patients who reacted by a sharp rise of temperature and a rigor, and then had lost their fever and recovered. He thought, however, that these measures should only be tried in severe cases. There had been a remarkable decrease in the incidence of typhoid fever since he had started work at a fever hospital. Paratyphoid B infection was very mild compared with typhoid, and for the sake of the prognosis it was always worth while to differentiate them serologically.

Dr. A. CAWADIAS said he had seen many cases with sudden onset, accompanied by rigors, in Paris and Athens. In Paris this onset was due to defective immunity and indicated a grave prognosis; in Greece it was due to the malarial soil and patients did well. Simple typhoid vaccine produced very marked reactions in patients who had had malaria and also awakened their malaria: he had given quinine after typhoid inoculation as a routine in Greece. He did not think typhoid was more benign in the malarial patient. He mentioned a form he had seen—chiefly among children—associated with intense diarrhoea and very severe symptoms; post mortem there would be intense ulceration of the colon, resembling dysentery or paratyphoid. He thought this was due to secondary auto-infection by the putrefactive bacteria, giving an appearance of colo-typhoid. In Greece the agglutination test could not be relied on as so many people had had typhoid already. He had tried many treatments; vaccines never gave definite results, and the physician who used them always had before him the ghost of the negative reaction. He advised adherence to the classical methods.

Lieut.-Colonel W. B. ALCOCK said that the laboratory worker must join forces with the clinician. Paratyphoid B simulated pneumonia more often than typhoid. He had once recovered the typhoid bacillus from an abscess of the thigh and it was not uncommon in the muscles. Gallipoli cases had been very mixed infections—typhoid, Shiga, and *Amaba histolytica*. He had seen five infections in one man. He did not do agglutination tests to titre because of the zones of inhibition.

Dr. SCOTT, in reply, said that a colon infection was not necessarily dysenteric; it might be paratyphoid B, which could simulate dysentery very closely.

Dr. DAY, in reply, pointed out that a relapse might be due to excretion of bacilli with the bile. Vaccine treatment remained experimental and the whole subject of immunity needed transferring from the study of the blood to the study of the tissues.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF PATHOLOGY.

A MEETING of this Section was held on Nov. 30th when Dr. T. T. O'FARRELL, the President, exhibited a specimen of

Bothrioccephalus Latus.

It was, he said, the third which he had encountered, the previous ones being recorded in 1916¹ and 1918.²

The patient, a man aged 36, from whom the specimen was obtained, was born in County Leitrim, where he spent the first 11 years of his life. He subsequently lived in Belfast (10 years), Blackburn, England (3 years), and Belfast again (3 years). He frequently returned to his original home on vacation though he had never been abroad. Seven years ago he passed segments of a tape-worm (not identified). In September, 1925, he passed more segments, and was treated with filix mas, after which he passed the

² THE LANCET, 1918, i., 570.

infected with bilharzia. Duvé⁷ and later Dew⁸ found a marked eosinophilic reaction of the endothelial cells and leucocytes round the growing hydatid cyst in the livers of artificially infected pigs.

3. The mode of infection is usually by impure water or infected uncooked vegetables, such as watercress. In Duffek's case,² as in the present one, the infection began in October or the beginning of November, and the summer of 1901 like that of 1927 had been very wet and liver fluke had been a common disease of the sheep in the districts in which the cases occurred. As early as the fourteenth century the disease in sheep was described by Jehan de Brié⁹ in his book on "the whole art of shepherding," "Traicté de l'estat, science et pratique de l'art de Bergerie, et de garder oïlles et brebis à laine," published in 1379, and presented to the learned King Charles V. Chapter xxviii. of this book deals with "Dauve, a small herb (*Ranunculus lingua* and *R. flammula*) which by corruption when eaten engenders a sort of worm, which gets into and destroys the liver. Therefore the shepherd must keep his sheep away from marshes and low pastures in the month of March." It is now known that the infection is carried by water and uncooked vegetables, and that the pond snails (*Limnææ*) act as intermediate hosts.

A CASE OF RUPTURE OF THE ŒSOPHAGUS BY INDIRECT VIOLENCE.

By J. R. MURDOCH, M.B. EDIN.,

FIRST ASSISTANT MEDICAL OFFICER, NORTH MIDDLESEX
HOSPITAL, N.

THE following case of rupture of the œsophagus seems worthy of record:—

A boy, aged 6 years, was admitted to the North Middlesex Hospital after having been knocked down and run over by a motor-cycle. When seen on admission he was quite unconscious, with hæmorrhage from the nose and mouth. He died a few hours after admission.

Post-mortem examination revealed marked bruising of left chest wall and over left hip-joint, extensive bruising of scalp on left side, and a comminuted fracture of left humerus. The heart, larynx, and trachea were normal. Left pleural cavity was partially filled with dark reddish-brown fluid containing small particles of food. The base of the left lung was collapsed and very congested. No ribs were fractured, and the right pleural cavity and lung were normal.

A longitudinal tear was found on the left side of the œsophagus $\frac{1}{2}$ in. above diaphragm and $1\frac{1}{2}$ in. long. There was also a slight rupture of the diaphragm around the œsophageal opening. The œsophageal wall was extremely thin. The abdominal organs were all normal with no signs of injury. A large fracture of the skull was found running from the vault on the left side down into the left middle fossa, and there was an extensive extradural hæmorrhage on the left side.

It would appear from the examination of this case that the motor-cycle wheel passed over the boy's chest and in this way stretched the diaphragm around the œsophageal opening, with the resulting rupture of the diaphragm and the œsophagus above it. A few cases of spontaneous rupture of the œsophagus have been recorded and usually the tear has been longitudinal, but very few cases of rupture by indirect violence can be found in the literature. In this case the œsophageal wall was extremely thin, but showed no evidence of gross disease in any part.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF TROPICAL DISEASES.

At a meeting of this Section held on Dec. 6th Dr. J. G. THOMSON took the chair, and a discussion on

CLINICAL AND PATHOLOGICAL CORRELATION IN TYPHOID AND ALLIED DISEASES

was opened by Dr. H. H. SCOTT, who illustrated his points by relating cases from his own experience. Typhoid, he said, was such a protean disease that the typical symptoms might be either in abeyance or so overshadowed by some symptom or syndrome that the true nature of the malady might escape the doctor. Sometimes these anomalies might be accounted for in the post-mortem room. The first anomalous group was that marked by unusual modes of onset or in which some prominent symptom led the observer off the scent. He gave three examples of this: (1) *Onset with a chill*. He had seen a white woman of 27, eight months pregnant, who had got up quite well in the morning and had a shivering fit at 10 A.M. which had lasted for an hour. At the end of it labour had begun and a healthy infant had been born. The mother had then gone on to typical typhoid fever. In another case—which would also serve as an example of pneumotypoid—a native boy of 19 had been ill for several days before he saw the doctor, and by that time he had all the signs of lobar pneumonia. Consolidation had been found post mortem, but so also had typhoid ulcers. (2) *Signs of peritonitis*. A native of 20 had died with the signs of general peritonitis. At autopsy the peritonitis was found to be the result of perforation of a typhoid ulcer. The lad had apparently felt no serious discomfort before the perforation. (3) *Ambulatory Forms*. There was no doubt that the man who kept about in the early stages of typhoid was running a very grave risk; the mortality-rate was largely kept up by these cases. Dr. Scott illustrated this type from his own attack of typhoid. After ten days of severe headache and rising temperature he had examined the agglutination of his serum, but it had been negative, and was again negative five days later. On the seventeenth day of the illness, with a temperature of 103.6° F., he had had to travel several miles to give evidence in court, and had gone to bed on his return. So severe had the attack been that the temperature was not normal until the sixty-third day. The blood had given no reaction until the second relapse on the forty-eighth day.

The second group of anomalous cases was that in which special symptoms or unusual complications appeared. The first type was the nervous one. True meningitis might occur, more often serous than suppurative. He had seen a hemiplegic negro in whom the brain had been found normal post mortem, but typhoid ulceration had been present in the intestine. A Canadian man had developed local neuritis of both legs in his third attack of typhoid—a very severe one with two relapses, three severe hæmorrhages, and a temperature of 105°–106° for six days. He had had very tender toes and excruciating pain in the calves and feet. Two years later there was still abnormal fatigability and numbness. The second type was when peculiar forms of fever occurred. He had seen three afebrile cases, all exceptionally severe, and inverse and intermittent fever. Anomalous temperature charts might be the result of multiplication of the bacillus in the meninges, the kidney, or the biliary system. The third was masking of the basal condition by coincident disease. Typhoid might occur in a tuberculous patient or might localise early in the lungs, and tuberculosis might simulate typhoid. In malarial subjects the advent of typhoid might be preceded by paroxysms indistinguishable from *arvus*, except that quinine did not check them. Any disease supervening on malaria was apt to assume an inter-

DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE.

Third edition. By Sir KENNETH GOADBY, K.B.E., L.R.C.P., M.R.C.S., L.D.S., Lecturer on Bacteriology of the Mouth, Dental Department, University College Hospital. London: Humphry Milford, Oxford University Press. 1928. Pp. 412. 42s.

THIS book affords a useful conspectus of dental disease for the doctor, and at the same time provides the dental reader with a good account of oral conditions. The chapter on general diseases originating from mouth affections has been revised and considerably improved. A few fresh illustrations have been added to other sections of the book. Here and there are minor alterations in the letterpress but otherwise the changes in this edition are slight. In the chapter on periodontal diseases there is no reference to the work of B. Gottlieb and H. K. Box which has considerably modified our views on the pathology of pyorrhœa. The brief account of lymphatic leukaemia might well have included a reference to the fact that there is a serious liability to intractable hæmorrhage from the mouth in this disease: a considerable literature has now accumulated to show that many of the cases of fatal bleeding after tooth extraction have really been due to lymphatic leukaemia and that the oral sepsis which made the extractions necessary is itself a manifestation of the leukæmic condition.

The book ranks as an important contribution to stomatology.

SPECIAL MEDICAL PATHOLOGY AND THERAPY.

Strümpell-Seifarth Lehrbuch der Speziellen Pathologie und Therapie der inneren Krankheiten. Twenty-seventh edition. By CARLY SEIFARTH, M.D., D.Ph., Professor für innere Medizin der Universität, Leipzig. Leipzig: F. C. W. Vogel. 1928. Vol. I., pp. 872. Vol. II., pp. 989. M.25 each vol.

Prof. Seifarth has revised for the third time since the death of Strümpell this excellent and comprehensive manual, which has been famous since 1883. We are not surprised to learn that it has been translated into English, French, Italian, Spanish, Greek, Turkish, and Japanese, with a pirate edition in Russian. In the twenty-seventh edition the sections on dysentery, septicæmia, tetanus, asthma, pulmonary tuberculosis, pyelitis, and pernicious anæmia have been rewritten. The total bulk of the book remains the same, partly because more sections have been put into small type. It is illustrated by 384 pictures and 16 plates: 93 of these are new, and have chiefly replaced old ones. Most of the illustrations are so well chosen that they command attention; for example, a coloured picture of the smooth atrophy of the tongue in long-standing pernicious anæmia conveys a wonderfully accurate impression of that condition. There are many other clinical photographs and radiograms of which the same may be said. The treatment of each subject is, wherever possible, primarily from the standpoint of its morbid anatomy. Some topics are well served by this method. For example, we are told in a brief paragraph that mesoarteritis syphilitica is most marked at the beginning of the thoracic aorta and ends abruptly, is discovered by fine longitudinal creases in the intima with irregular flat bluish-white thickenings which may obstruct the coronary orifices, and that histologically the main change is inflammatory. The complications are then discussed, and there follows a description of clinical types, radiological appearances, diagnosis, and treatment. Other types of arterial disease are dealt with in the same thorough manner; but surely a compatriot of Pick should revise the statement that military aneurysms play an important part in cerebral hæmorrhage! The section on tetany has been brought up to date so that over-ventilation and parathyroid extracts are given a place. The clinical descriptions are excellent, and the accounts given of endemic tetany and "die Arthrogrypose" are so realistic that the English

reader who has probably never seen them is well able to visualise them. Similarly, the cataract of post-operative tetany is graphically described. But it is hardly true that in tetany the serum calcium is always diminished. For ourselves we would be happy to find the pathology so simple. In the present state of our knowledge the classical German method of starting with morbid anatomy is not appropriate to this section of the book, and it should be rewritten on the basis of a chemical classification in which tetany with low serum calcium should be clearly differentiated from tetany with alkalosis. The sections on gigantism, eunuchoidism, pineal tumours, and the adrenal-genital syndrome are well written, and that on hypophyseal cachexia (Simmondssche Krankheit) is a welcome addition.

The paper, printing, and indexing are alike admirable. We heartily recommend this publication to all who are seriously interested in medicine, and we can only wish that in its forty-fifth year it may again be translated into English.

ULTRA-VIOLET RADIATION AND ACTINOTHERAPY.

Third edition. By ELEANOR H. RUSSELL, M.D., B.S., and W. KERR RUSSELL, M.D., B.S., Hon. Director, Sun-Ray Clinic, Newcastle-on-Tyne. Edinburgh: E. and S. Livingstone. 1928. Pp. 648. 21s.

IN its third edition this work has been much enlarged and has assumed a more ambitious character. It is no longer a concise introduction to actinotherapy, but a review of the physical and biological facts on which actinotherapy is based and of its clinical application. Since at present only a bare nucleus of facts have been generally accepted in this branch of therapeutics, it is perhaps premature to attempt to embody recent work, which still lacks confirmation, in a text-book, especially where limitation of space does not permit of critical discussion. The authors do not always make it clear whether their statements are based on their own experience or on the deductions of other workers; this is unfortunate, especially when they deal with controversial matter. In the clinical section they give illustrative cases from their own practice: if space had permitted survey of their cases as a whole, under the heading of each disease treated, it would have been a useful addition to this chapter. The book contains clear descriptions of lamps and apparatus, and many illustrations and useful diagrams. It will prove of value to anyone engaged in the study of actinotherapy.

THE DERMATOGESSES OR OCCUPATIONAL AFFECTIONS OF THE SKIN.

Third edition. By R. PROSSER WHITE, M.D., C.M. Edin., M.R.C.S. Eng. London: H. K. Lewis and Co., Ltd. 1928. Pp. 734. 35s.

EVERY chief of a dermatological clinic is aware that a growing percentage of his material is the result of irritation from dust and liquids: he is, indeed, often requested either by the patient or his medical attendant to give testimony to this effect. Some conception of the enormous scope of occupational affections of the skin to-day may be gathered from the index to this treatise, which occupies more than 200 of its 700 pages. The bibliography quoted is immense, and there are references to current literature on nearly every page of the letterpress. Such a method of handling the subject provides the reader with a most valuable encyclopædia, and one which will doubtless continue to be in constant demand by insurance companies and in the law-courts. This exhaustive method has its corresponding disadvantages. Such a well-documented treatise does not make a readable book. Moreover, over-emphasis, many italics, and the too frequent use of a thick type defeat their object of stimulating attention. As far as can be ascertained from a short survey of the contents there is no known external cause of cutaneous or mucocutaneous irritation which has escaped discussion or

present specimen which appeared to be the entire worm, though the head was not recovered.

The patient never exhibited any noticeable anaemia. A blood examination in November gave the following figures: red cells, 4,440,000; haemoglobin, 96 per cent., colour-index, 1.0; white cells, 9280. Stained films showed slight anisocytosis with an occasional microcyte but no poikilocytosis. No nucleated red cells were found. The differential leucocyte count per cent. was as follows: small lymphocytes, 20; large lymphocytes, 14; hyalines, 10; polynuclears, 52; eosinophils, 2; basophiles, 2.

As in the other cases from the County Leitrim area, said the President, there was practically no anaemia and no eosinophilia. The patient had eaten freely of fresh-water fish, including pike, and also had an unusual predilection for raw meat.

Dr. J. T. WIGHAM said he thought the patient must have eaten raw fish, as he did not think that cooked fish caused the worm to appear. He thought that the host must be some animal other than man, or else the worm would have died out.

Dr. J. SPEARES asked if the head of the worm had been found, and, if so, whether there had been difficulty in finding it.

The PRESIDENT, in replying, said that the patient stated he never ate anything but thoroughly cooked fish, but it was evident that this was not the case. He thought it possible that this worm was fairly common and should be treated as an ordinary tape-worm. The head of the worm had not been found, and he personally was not satisfied that the worm had gone.

Dr. SPEARES read notes on a Case of Cancer in the Lung, and Mr. F. J. HENRY reported a case of Lymphosarcoma, specimens in each case being demonstrated by Dr. Wigham. Dr. A. B. CLERY showed an Adenoma of the Breast, and Dr. R. A. O. O'MEARA read a paper on Boveri's Reaction on the Cerebro-spinal Fluid.

Reports and Analytical Records.

STANIFORM.

(WHIFFEN AND SONS, LTD., CARNWATH-ROAD, FULHAM, LONDON, S.W.)

STANIFORM is a proprietary name for methyl stannic iodide. This new therapeutic agent is supplied (a) as an ointment consisting of vaselin with which is incorporated 2 per cent. of methyl stannic iodide, and (b) as a dusting powder composed of talc mixed with 5 per cent. of the iodide. On analysis figures rather lower than these were obtained owing to technical difficulties incidental to the analysis of so volatile a material. Methyl stannic iodide is a bright yellow crystalline powder practically devoid of odour, and possesses the advantages of not staining fabric. It has the formula SnCH_3I_2 , and the specimen sent to us was of 95 per cent. purity, the balance probably being moisture. It is interesting to note that the molecule consists of 23 per cent. of tin and 74 per cent. of iodine.

Staniform is antiphlogistic, analgesic, and antiseptic in its properties. The use of tin is well known in staphylococcal infections and here it is combined with the potent germicidal properties of iodine. Staniform is of considerable benefit in local inflammations, and is claimed to induce an immediate soothing effect with rapid healing.

ABERDEEN MEDICO-SURGICAL SOCIETY.—The annual business meeting of this society was held on Nov. 22nd, with Dr. Thomas Fraser, the retiring President, in the chair. The following office-bearers were elected:—President: Prof. Alexander Low; Vice-President, Dr. Charles Forbes; secretary, Dr. Harold Edgar Smith; treasurer, Dr. Robert Richards; editor of transactions, Mr. George Herbert Colt. The following were elected members of council: Dr. John Farquhar Christie, Dr. George Rose, Dr. William Brown, Dr. William Clark Souter, Dr. Frederick K. Smith, Dr. George Swapp, Dr. John Smith, and Dr. Thomas Fraser. Prof. Low was invested and installed in office.

Reviews and Notices of Books.

DISEASES OF THE INTESTINE

Including the Liver, Gall-bladder, Pancreas, and Lower Alimentary Tract. Third edition. By ANTHONY BASSLER, M.D., F.A.C.P., Consulting Gastro-enterologist, St. Vincent's Hospital, New York City. Philadelphia: F. A. Davis Company. 1928. Pp. 905.

THERE are two methods of producing fresh editions of books on a rapidly developing subject. Either the whole work is cast into the melting pot, with the result that practically a new book is produced, or, additions are made here and there, and extra chapters written, to bring the contents up to date. Prof. Bassler has adopted the second method in the third edition of this work which has the disadvantages associated with the sewing of new patches on old garments. But his main idea of studying digestion below the pylorus as a whole is such a good one that these are soon forgotten. The first 200 pages cover a brief study of the anatomy, physiology, and chemistry of the alimentary canal, from pylorus to anus, with a short description of clinical examination, history-taking, radiography, and the investigation of duodenal contents, stools, &c.; the technique of the tests mentioned being briefly described. A fine discrimination is exercised in estimating the value attaching to clinical examination on the one hand and ingeniously devised tests on the other. Thus while a warm tribute is paid to Vincent Lyons for his work on non-surgical biliary drainage, the author advises physicians not to depend on this or any other method of diagnosis alone, and not to lay too great stress on its significance when estimating the pathology of the gall-bladder in any individual patient. The book embodies the clinical experience of a highly trained and careful observer and herein lies its chief appeal. The opinions and theories of others are clearly set out, but again and again the author falls back on what he himself has seen, felt, or noted. Having supplied the data, Prof. Bassler argues the case with the reader in a logical way, and even where he does not carry conviction, he provokes thought. Nearly a hundred pages are devoted to "chronic excessive intestinal toxæmia," and include a long and detailed description of the fæces found in this condition; the reason for this becomes clear in the discussion on treatment, for Prof. Bassler believes strongly in autogenous vaccines. Much doubt has been thrown lately on the reliability of faecal cultures; if they are to be of value, they require a technique beyond the powers of any but specially trained workers. It may be noted in passing that, with the exception of some of Prof. Bassler's own articles, the references at the end of each chapter all date from before 1920. It is especially to be regretted that so little mention is made of recent work on this side of the Atlantic. To quote but a few instances, the omission of D. P. D. Wilkie's work in connexion with the gall-bladder and duodenal ileus, of that of E. I. Spriggs and O. A. Marxer on diverticulitis, and of van den Bergh and J. W. McNee on jaundice will puzzle British readers. The sections on radiology are on the whole particularly good, but we noticed no mention of the need of rotating the patient to get all parts of the bowel in profile. The radiograms reproduced are carefully selected and well produced, but are arranged without much method. Thus there is no uniformity in the position of the patient relative to the reader whose right side may or may not coincide with the patient's right side. These are small blemishes and the discriminating reader will find the work a useful addition to his library. It is characterized by common sense and an observance of established principles, and, while the author advocates the views he holds himself, he is not intolerant of those advanced by others.

THE LANCET.

SATURDAY, DECEMBER 22, 1928.

THE KING'S ILLNESS.

More than four weeks of illness the KING still demands and obtains the first place in the public mind. Bringing a sense of deep strain into the hearts of his subjects and fellow-countrymen, and of the exhaustion resulting therefrom must make progress slow and difficult. At the same time dangerous phases of the illness have been surmounted and there are increasingly solid grounds for hoping that recovery will result from this long and anxious struggle.

So immediate and definite a change, from the present state of the case, was more than could be expected but the following authoritative statement to the medical profession shows that this dangerous illness has reached a stage where a reasonable probability of improvement exists.

Wednesday, Dec. 19th, at 8 P.M.

are signs that the KING's illness is progressing towards an understanding of the future course of the illness. It will be apparent to medical men that not only the severity and length of the infection but the exhaustion resulting therefrom must make progress slow and difficult. At the same time dangerous phases of the illness have been surmounted and there are increasingly solid grounds for hoping that recovery will result from this long and anxious struggle.

Neuralgia, of the case, was more than could be expected but the following authoritative statement to the medical profession shows that this dangerous illness has reached a stage where a reasonable probability of improvement exists.

Wednesday, Dec. 19th, at 8 P.M.

Neuralgia, of the case, was more than could be expected but the following authoritative statement to the medical profession shows that this dangerous illness has reached a stage where a reasonable probability of improvement exists.

Wednesday, Dec. 19th, at 8 P.M.

are signs that the KING's illness is progressing towards an understanding of the future course of the illness. It will be apparent to medical men that not only the severity and length of the infection but the exhaustion resulting therefrom must make progress slow and difficult. At the same time dangerous phases of the illness have been surmounted and there are increasingly solid grounds for hoping that recovery will result from this long and anxious struggle.

from a mercury lamp has been made each day since Dec. 15th. The effect of these exposures is being checked by leucocyte counts and estimation of the bactericidal power of the patient's blood. There is reason to think that this employment of the ultra-violet rays has in combination with the treatment mentioned in previous statements been beneficial.

“It is hoped that the foregoing account will help towards an understanding of the future course of the illness. It will be apparent to medical men that not only the severity and length of the infection but the exhaustion resulting therefrom must make progress slow and difficult. At the same time dangerous phases of the illness have been surmounted and there are increasingly solid grounds for hoping that recovery will result from this long and anxious struggle.”

The following medical men in addition to those previously mentioned have contributed to the KING's care during the past weeks: Sir Hugh Rigby, Dr. Francis Edward Shipway, Dr. Robert Stanton Woods, and Dr. Frank Dutch Howitt. The nurses are as before: Nurse E. Gordon (St. Thomas's Hospital), Nurse Catherine Black (London Hospital), Nurse Rosina Davies (London Hospital), and Nurse N. M. Purdie (Westminster Hospital).

DENTAL HEALTH EDUCATION.

THERE is something of a self-denying ordinance about the educational campaign carried out by the Dental Board of the United Kingdom, for the fruits of these efforts in the future should be such an improvement in the teeth of the nation that the originators will be deprived of their occupation. It is five years since the Dental Board decided to embark upon a campaign to educate the public in the importance of dental health. A committee investigated the question from November, 1923, until the following November, and early in 1925 a large and representative conference was convened at which a full and valuable discussion ensued. The details of propaganda were worked out by subcommittees, and the experience thus gained should prove useful to other public bodies who contemplate similar campaigns. The scheme may be studied in a report¹ by the Board's secretary for education, entitled *Progress in Dental Health Education, 1924-28*.

Films prepared for the Board, though mainly intended for juvenile audiences, are extremely well received by adults, and the returns show that copies of the films had been booked out about 120 times a year. It is found that the expense entailed prevents their being placed on regular cinema circuits for public exhibition, and their main use is for the children. Here, the Board maintains, is the most important field for educational work, and first a leaflet and, later, a book entitled *Hygiene of the Mouth and Teeth* have been circulated to the teaching profession throughout the country. The educational value of such leaflets is regarded as uncertain: nevertheless in connexion with the National Health Week in 1927 some 100,000 leaflets were distributed, and in 1928 more than double that number. The Board has made lectures one of the main features of its campaign. The method adopted has been to coöperate with various organisations, such as the British Red Cross Society and the Industrial Health Education Society in securing the audiences which it might otherwise be difficult to reach.

¹ Issued from the office of the Dental Board, 44, Holborn street, London, W.

at least mention; those who want more details can find them easily by referring to one or more of the original papers quoted in the footnotes. The twelve chapters deal successively with the action of physical agents (such as water, light, and X rays), acids, alkalies, metallic salts, the hydrocarbon series, mineral and vegetable dusts, special trades, synthetic dyes, plant irritants, and dermatitis due to animal and mould infections. Finally there is a useful section on war dermatoses. The meticulous industry of the author and his assistant, Miss Anne Newbold, is admirably illustrated by the article on the irritant gases which is not included under war dermatoses. This article alone would make the book a valuable and almost indispensable addition to every dermatological library. The illustrations, most of them reproduced from actual photographs, are technically perfect, but the lawyer and even the practitioner should be wary of basing an opinion on the clinical evidence afforded from these, for a "dermatitis artefacta" may show even less concrete and standard manifestations than the classical lesions in the field of dermatopathology. The author concludes with a full glossary of (mostly) dermatological terms, for which even the more expert reader will be grateful, since terminology has always been a stumbling-block in the study of skin diseases.

The book has passed through three editions since it first appeared in 1915; there have been two American impressions and a Russian translation. Dr. Prosser White deserves this success, for there are few more complete compilations in any special subject in the domain of British medicine.

THE DIAGNOSIS OF CHILDREN'S DISEASES.

Second (English) edition. By Prof. E. FEER, Zurich. Translated by C. A. SCHERER, M.D., F.A.C.P. London: J. B. Lippincott Company. 1928. Pp. 551. 35s.

THE success which we predicted for Dr. Scherer's translation of this well-known continental work is evidenced by the exhaustion of the first edition and the appearance of the second within three years. The work is concerned with clinical diagnosis, not with pathology or treatment, and consequently has required few significant alterations in the new edition. The size and form of the book have undergone little change, but numerous minor additions have been made to the text. A notable feature of the book is the excellence of the photographs, of which there are over 250. As a companion volume to a systematic text-book this work should continue to be of great value to students and practitioners.

A TEXT-BOOK OF FRACTURES AND DISLOCATIONS.

Second edition. By KELLOGG SPEED, S.B., M.D., F.A.C.S., Associate Professor of Clinical Surgery, University of Chicago. London: Henry Kimpton. 1928. Pp. 952. 50s.

THE aim of the writer of this text-book, as outlined in his preface, has been to present an account of practical and accepted methods of fracture treatment, avoiding fads. The principles outlined bear for the most part the stamp of common sense; the apparatus advocated is simple and practical. Where operation is advised, there is a commendable insistence upon the need for the most rigorous asepsis in dealing with bones and joints, a need not always sufficiently stressed by writers on fractures.

While the principles underlying Prof. Kellogg Speed's teaching are thus admirable, their presentation is less satisfactory. The book reads like a series of shorthand notes taken from lectures and printed without abridgement or revision rather than like the second edition of a serious work. In no section, except possibly that upon injuries of the wrist, to which those already acquainted with the author's writings will immediately turn, is there any orderly sequence. The first three chapters, which deal with

general principles, leave the reader entirely confused. The essential matter which they contain could be expressed in half a dozen pages; the remainder is detail out of place. But throughout the book the same confusion is evident. The sections on head injuries, fractures of the clavicle, and fractures of the neck of the femur are particularly bad. The essential teaching is there, but it is so overlaid by repetition and confused by lack of clear arrangement that only the expert can find his way through the maze. A fictitious appearance of clarity is given by the large number of headings, which may have little reference to the matter which follows. The use of slang may be permissible, but its appearance in a text-book is an æsthetic error.

The illustrations on the whole are good. One cannot but regret that the author's very considerable experience is not presented in a more attractive form.

A COLLEGE TEXT-BOOK OF HYGIENE.

By Dean FRANKLIN SMILEY, A.B., M.D., Medical Adviser and Assistant Professor of Hygiene in Cornell University; and ADRIAN GOULD, Ph.B., M.D., Assistant Medical Adviser and Assistant Professor of Hygiene in the University. New York: The MacMillan Company. 1928. Pp. 333. 8s. 6d.

This book, written by members of the staff of one of the leading universities of the United States, contains material derived almost exclusively from American sources, including questionnaires issued to Cornell undergraduates. During the past seven years the authors have lectured on personal and community hygiene to the students of the Cornell University in order to induce them to take steps to preserve their own health and to disseminate a knowledge of hygiene. No claim is made that the ground is covered exhaustively or even that it is mapped out in the best possible way. Admittedly, this kind of teaching must be dogmatic, but in their endeavour to be up to date, the authors have included many statements which have not yet gained the support of the best informed members of the profession. The book is consequently unsuitable as a text-book, although most of the information given therein is sound; it deals with live problems, and will prove useful and stimulating if read with caution by the already well-informed. The illustrations have been well selected.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE. November, 1928.—An interesting experiment is recorded by N. H. Mummery, who inoculated 79 employed persons with anticatarrh vaccine in the autumn. Out of this group 51 per cent. developed acute coryza compared with only 25 per cent. out of a control group of 72 persons. The inoculations are thought to have been given too late in the season and so the phase of increased susceptibility synchronised with increased opportunities for infection.—Certain data are given and discussed by R. M. Hutton relating to the occurrence of respiratory disease in industry, and the deduction is drawn that the worst respiratory mortality is associated with dust and particularly silica dust. Extreme heat with sudden variations in temperature and exposure to weather are also shown to be injurious.—An inquiry is described by J. Meyers into the hazard of benzol poisoning arising from applying paint by spray. Abnormally low leucocyte counts, characteristic of this poison, were found in 29 per cent. of the men examined, while in 21 per cent. the spleen was palpable, an unexpected observation.—The occurrence of phosphorus necrosis in America is reported by E. F. Ward in the manufacture of fireworks. At three factories, among 56 females employed, 11 cases, two of which were fatal, were discovered. Some of these horrible cases are described and figured. Discontinuance of the use of yellow phosphorus is now promised by the trade. It should be prohibited by Federal Law, as in the case of matches.

diseased viscus, it should follow that when the cutaneous afferent impulses are blocked by intradermal injections of novocaine, the referred pain will be abolished. If the pain is visceral in origin it should persist after the injections, and if visceral and referred pains are both present, the composite pain should be reduced proportionately to its referred element. They found in many forms of visceral disease that if the pain was sufficiently localised, it could be greatly lessened after infiltration of a small area of skin with novocaine. Sometimes after the cutaneous afferent impulses had been blocked, certain unpleasant sensations—but not definite pain—were experienced, and these WEISS and DAVIS regard as true visceral sensation. They suggest that the analgesic effect of paravertebral injections ostensibly designed to infiltrate the rami communicantes of the sympathetic chain is really due to blocking of cutaneous impulses going to the spinal cord; and, further, that infiltration of the skin with novocaine is a practical therapeutic measure in some pathological conditions associated with localised pain.

THE LIMITATIONS OF SANATORIUM TREATMENT.

It is written that those who are whole have no need of the physician, but only the sick. The practice at certain sanatoriums would suggest an inversion of the text, for the patient with the demonstrable signs of disease is not wanted. It is therefore refreshing to read of an institution where all sufferers from pulmonary tuberculosis are equally welcome. Dr. P. C. Varrier-Jones,¹ in the annual report of the Papworth Village Settlement, makes it clear that his institution is not reserved for the treatment of the so-called early case. On the contrary, his object is to provide for permanently damaged lives, for "substandard men and women who cannot be employed in the industrial and commercial world." He is much more concerned with the need of the sufferer than with a reputation for miraculous cures. We are frequently told that the early case of pulmonary tuberculosis is eminently curable. This is one of those half-truths from which false deductions are constantly made. If the patient possesses a fair natural resistance, if he can command all the conditions necessary for complete repose of body and mind, if he has sufficient intelligence to understand and sufficient determination to follow the method of life necessary for a cure his prospects are hopeful. For the average industrial worker smitten with tuberculosis the prospect is well-nigh desperate. It is perhaps unnecessary to add that we are not referring to the early case whose sputum has never revealed the tubercle bacillus, to the tuberculous ex-Service man whose disease begins and ends in a series of dossiers and record cards, nor to the rare abortive types of disease whose course is self-limited whether treatment be given or withheld. The current teaching concerning the early case involves a fallacy. The onset of pulmonary tuberculosis in the adolescent and young adult is usually rapid, and the incipient stage may give rise to neither symptoms nor physical signs. The patient has had a clean bill of health and even a routine skiagram may have shown no abnormality within a few weeks of the outbreak of serious disease. It is noteworthy how often the young patient states that the first symptoms

immediately "followed an attack of influenza." Within a few weeks of the onset the sputum is loaded with tubercle bacilli, physical examination detects widespread disease, the skiagram reveals abundant areas of mottling and hazy opacities below the clavicles or external to the root shadows. It is true that modern methods of treatment, notably collapse therapy combined with a prolonged period of careful supervision, may result in permanent arrest of disease that otherwise would prove fatal. The fact is attested by records of notification and death that a majority of consumptives die within a few years after the onset of symptoms of ill-health. For those who return from a sanatorium to unfavourable home conditions the outlook is almost hopeless. When in the annual report of a well-known sanatorium we read that 85 per cent. of the early cases were discharged "fit for work" and 48 per cent. of all cases discharged were in a similar happy condition, we can only infer that diagnosis has been at fault or that cruel disillusionment awaits those who return to office, factory, or field. It is noteworthy that the report contains no reference to sputum examinations.

It is common knowledge that pulmonary tuberculosis in the middle-aged tends to run a chronic course. The sufferer from fibroid phthisis usually remains at work for long after the disease has become firmly established. But a time comes when increasing cough and loss of strength drives him to panel doctor or tuberculosis dispensary. The response to sanatorium treatment is gratifying, symptoms decline, the patient gains in weight, the temperature remains normal despite increasing exercise, and at the end of a few months' treatment he is discharged. Return to work is followed by a recurrence of symptoms—and so back to the sanatorium. The records of the dispensaries tell a tragic story of wasted effort and frustrated hope. The Ministry of Health has often stressed the need for the after-care of those discharged from sanatoriums, and this is emphasised once again in that section of the report of its Chief Medical Officer which is devoted to tuberculosis (see p. 1313). After-care, which is confined to occasional calls by a health visitor, occasional examinations at the dispensary, occasional doles from charitable committees, is futile. It is notorious that the consumptive cannot hope to find work in the open market. Yet without work he will be reduced to penury and despair. Meanwhile his family must be exposed to massive infection at a time when poverty is undermining health, and in due time a similar tragedy will be repeated in the next generation.

The village settlement with its ideal homes and sheltered trades, with its hospital wards and sanatorium where those who relapse can receive all that medical skill can effect, separated from and yet in touch with their friends, is the most hopeful experiment yet made on behalf of the tuberculous. At Papworth and Preston Hall the experiment has proved a notable success. Two arguments may be adduced against an extension of the system to other areas in the country. In the first place, schemes of this kind are very costly and require lavish endowments, and in the second, previous experiments in treatment and training elsewhere have failed. The average consumptive lacks persistence and fails to achieve the self-discipline without which restoration of working capacity is impossible. The financial difficulty is perhaps not insuperable, and with regard to the personal factor, while admitting that only the brave and determined can hope to overcome the disabilities of chronic ill-health, we may well ask ourselves whether two institutions suffice to meet the needs of all those who are both willing and able to work if work is adapted to their strength. Are we content to leave such in the dungeons of Giant Despair?

¹ Reports of the Committee of Management and Medical Director of the Papworth Village Settlement for 1927.

VISCERAL PAIN.

WHETHER the internal organs can feel pain is a question that has long given rise to controversy. The doctrine that they have no such sensibility seems contrary to common experience and strikes the man in the street as absurd; if he has abdominal colic he feels pain inside him, quite apart from any additional sensation referred to the body wall. Yet this same doctrine has been current for a long time. As far back as 1763 HALLER concluded that there was no evidence that the viscera were sensitive to painful stimuli, and though his views were ignored until operations came to be performed under local anaesthesia, the conception of referred pain was quite well known in England about the middle of the last century. HILTON, for instance, in 1863, suggested that superficial pain in visceral disease might be due to a central connexion between the visceral sympathetic nerves and the peripheral sensory nerves; MARTYN, in 1864, said that reflected or radiated pain was then recognised as extremely common; and in 1888 ROSS advanced the theory that there were two kinds of visceral pain—namely, the splanchnic, which was felt in the organ itself and the somatic, which was referred to the body wall. HEAD and MACKENZIE, working independently, suggested about the same time that nearly all pain in visceral disease is really felt in the superficial structures of the body. HEAD differed from MACKENZIE in that he believed that, although visceral pain was nearly always referred, there was also a low form of protopathic pain which was in reality true visceral sensation. MACKENZIE, with his flair for bold outlines, maintained that the internal organs had no pain sensibility whatever. LENNAXDER, in 1901, traced the pain of abdominal disease to an extreme sensitiveness of the parietal peritoneum and of the subserous connective tissue, whilst MACKENZIE subscribed to the view that the subserous connective tissue was sensitive, but held that all serous membranes, including the pleura and pericardium, were devoid of pain sensibility.

Most observers agree that the viscera are insensitive to such stimuli as touching, squeezing, cutting, and burning which produce very definite sensations when applied to the skin and body wall. The concept of referred pain in visceral disease is also generally accepted. The explanation for divergence in views on visceral pain and sensation is probably to be found in the teaching of the physiologists that for each type of sensation there are specific end-organs, nerve paths, and sensory receptor cells in the thalamus and cortex cerebri, and further, that each type of sensation is produced by the application of a specific and "adequate" stimulus. This specificity of the sensory mechanism has been evolved and adapted to meet the needs of each part of the body and of the organism as a whole. The senses of touch, of heat and cold, taste, and hearing all have highly specialised nerve-endings, coordinated nerve paths, and receptor cells. The internal viscera are carefully insulated;

it is to say, they are normally not called upon to respond to such stimuli as those which set up the usual sensations and reflexes in relation to the outer covering of the body, thus bringing the individual into relationship with the outside world.

LENNAXDER and MACKENZIE, in their experimental work, applied to internal organs the stimuli which cause pain when applied to the superficial structures of the body, and found, as in LENNAXDER's classical experiment on the liver and gall-bladder, that such stimuli as cutting, scratching, squeezing, and burning did not evoke pain in the viscera. But, in so doing,

as A. F. HURST pointed out, they failed to apply the adequate and specific stimulus. J. A. RYLE says that the stimulus required to produce pain in a hollow viscus is tension in the muscular element of its wall. He maintains that the increased tension results either from exaggerated contraction of the muscle-fibres or from their failure to relax adequately when intravisceral pressure increases; further, he holds that visceral pain when occurring alone or dissociable from attendant referred pains may be accurately localised by the patient. He regards persistent referred or somatic pain and hyperalgesia as an expression of organic visceral disease of an inflammatory nature.

It appears that tension is the specific stimulus to which nearly all the viscera respond, not only in the alimentary but in the respiratory and cardiovascular systems—a thesis illustrated by the tension theory of pleural pain recently advanced by H. A. BRAR of New York. Evidence is accumulating, too, that some forms of pain in disease of the lung are due to tension and distortion of the nerve-endings in the pulmonary parenchyma. Absence of pain has been noted when the nerve-endings have been destroyed, as in cavitation—a fact which was pointed out by HEAD in 1896. HEAD also showed that in lobar pneumonia the massive consolidation protects the nerve-endings from pressure from without or traction from within, and consequently that the pain in this condition is due entirely to involvement of the pleura. In bronchopneumonia pain may arise from the lung itself because the scattered patches of consolidation do not give the nerve-endings absolute immunity from ension. By applying the tension theory to angina pectoris POULTON, we believe, makes a valuable contribution which helps to unify the conceptions of visceral pain, as well as explaining satisfactorily the undoubted action of amyl nitrite as a therapeutic agent in this condition. His work with W. W. PAYNE leads him to suppose that all the sensations arising from the alimentary tract—such as nausea, sinking, and pain—probably have their specific end-organs. As regards the exact mechanism by which tension in the alimentary tract produces pain, there is some difference of opinion between the views set out in the Oliver Sharpey lectures and those of CHARLES BOLTON.¹ PAYNE and POULTON think that oesophageal pain results from a stretching force in the viscus, distorting the pain nerve-endings in the oesophageal walls. This pain, in their opinion, may be relieved either by peristaltic contraction which overcomes the stretch or by postural adaptation which increases the capacity of the organ so that tension is reduced. They say that pain more often occurs during the relaxation following a peristaltic contraction than during the actual muscular contraction. BOLTON rightly points out that it is hard to imagine that there is more tension during relaxation than during muscular contraction. They agree, however, on the essential fact, that visceral pain is due to tension.

The empirical use of counter-irritation for relief of pain receives a measure of scientific approbation from the work of PAYNE and POULTON, and in recent clinical studies WEISS and DAVIS² throw further light on it from a new angle. They point out that the relationship between cutaneous sensation and visceral function is probably reversible. If the conception of referred pain is correct and visceral pain is caused by normal afferent impulses from the skin entering a segment of the cord which has become irritable as a result of exaggerated afferent impulses from a

¹ THE LANCET, 1928, i, 1238.
² Amer. Jour. Med. Sci., 1928, clxxvi., 617.

Lund, was led to search for similar specimens in the various museums of Europe, with the result that 15 unreported examples were assembled. In examining the post-mortem records he was impressed by the frequency with which the cerebellar cyst was associated with angiomatous and cystic lesions in other parts of the body. The lesions found included cysts of the kidneys and pancreas, adenoma of the adrenal gland, and angiomatous tumours in other parts of the nervous system. In one case it appeared that the patient had had one eye removed eight years before death for what was diagnosed as arteriovenous aneurysm of the retina. The eye had been preserved, and when it was cut and examined histologically a small capillary angioma of the retina was discovered. By this interesting disclosure Lindau was encouraged to study angiomatosis of the retina, a rare malady with a familial tendency, and he found that approximately 20 per cent. of the patients suffering from this condition had been known to have intracranial complications. Since the publication of Lindau's paper several additional cases have been reported in which cystic hæmangioma of the cerebellum was associated with cystic and angiomatous lesions in other parts of the body. Cushing and Bailey⁴ re-examined the eyes of six cases of hæmangioma of the cerebellum that had been operated on at Cushing's clinic in previous years, and in one of these cases they found an unmistakable angioma of the retina that had been overlooked at previous examinations. Detailed inquiry by Fulton into the family history of this patient disclosed that the father and one aunt had died of "ruptured cystic sarcoma" of the brain.

The discovery of angioma of the retina in a patient who is suspected of suffering from intracranial tumour may now be said to have a distinct significance; it suggests that the patient has a cystic hæmangioma of the cerebellum, a benign lesion that can be removed at operation. As Cushing's case shows, the retinal angioma may be overlooked. It usually lies in the peripheral part of the retina, and it may give rise to changes, such as cyst formation, detachment of the retina, hæmorrhages, and retinitis proliferans, all of which render the primary lesion obscure. Fortunately, however, the retinal vessels passing from the optic disc to the tumour are excessively enlarged, and the artery often has a varying calibre. Such appearances call for careful examination of the peripheral retina.

Although the observations are still few in number, there is little doubt that Lindau's syndrome is an hereditary affection. Hitherto the information that any disease is hereditary has usually come from patients whose sphere of observation is limited to diseases, such as hæmophilia, that are easy of recognition. Among diseases that cannot be diagnosed by lay observers, there must be many in which heredity plays a part, and it is legitimate to expect that the more accurate pathological investigation and documentation of cases during recent years will furnish, as records accumulate, more and more evidence of the influence of heredity in disease.

HOOKWORM INFECTION IN THE STRAITS SETTLEMENTS.

A REPORT⁵ has lately been made by Dr. P. F. Russell on work done during 1925-26 in determining the degree of infection with nematodes, particularly with hookworms, in the Straits Settlements. The method of diagnosis was by Willis's salt floatation technique; the covering slide, measuring 3 by 2 in., was reversed before examination, random sampling of 20 scattered fields was made, and the eggs in them counted. It is significant that in these preparations distribution of ova is apt to be irregular, while the eggs lost in reversal have been found to vary between none and three-quarters of the total which originally hung from the slide. It is then clear that Russell's

statement that the method is less accurate than certain others is well founded; yet it is claimed that it suits the local microscopist, since it demands neither precision of movement nor unremitting attention, that it forms a reliable and useful guide to intensity of hookworm infection in groups of people, and that egg-counts can be made at the rate of 50 specimens daily. On the basis of these counts stools are, necessarily arbitrarily, graded into groups with 10, 30, 60, and more than 60, in 20 fields. Fifty specimens being taken as the daily limit of work possible for one local microscopist, it is calculated that to reach Clayton Lane's claim, that by the use of direct centrifugal floatation (D.C.F.) diagnosis can be made at the rate of 250,000 specimens a year for each centrifuge, 20 full-time dressers would be needed for diagnosis alone, whereas there have never been more than five in the Straits Settlements for all work. There is misunderstanding here, for Lane's method of mass diagnosis discards all counting as being unnecessary. Estimation of numbers of eggs can be carried through incidentally in D.C.F., but if this is rejected as unnecessary his mass methods would, he believes, allow of diagnosis at the rate mentioned by four men, only two of them being microscopists.

Russell's practical experience of anthelmintic treatment in the field pits itself against the rather academic suggestions of Lamson and others⁶ for the immediate treatment of carbon tetrachloride poisoning. Russell urges prompt emesis and purgation with stimulant and symptomatic treatment, while as a precaution purgation must always be effected within three hours of taking this anthelmintic. The treatment advised for general use is a mixture of carbon tetrachloride (2 to 2.5 c.cm.) and oil of chenopodium (1.5 c.cm.). The criteria for the identification of hookworm larvae are admirably put in Russell's paper. Mass treatment without coincident soil sanitation is likened to bailing a sieve-bottomed boat, universal use of a sanitary latrine constituting the only hope of eradicating infection. Yet mass treatment, it is pointed out, has two real advantages. The seeing of worms in his own stool is apt to stir the most lethargic to an interest sufficient to drive him to provide a latrine for himself and his family. Secondly, heavy infection, individual and general, is reduced, and this gain may perhaps be held until soil pollution is controlled.

THE AMBULANCE.

FROM every side, with every week, comes fresh evidence of the steady trend of the sick from home and home care to the hospital. We reviewed in our issue of last week the opinions expressed by Mr. R. G. Hogarth on the future of paying annexes to all general hospitals, and the proposed amendment in the poor-law is going to thrust on the local authorities of every district a large number of hospital beds, not all of which need be kept for the destitute sick. Everybody concerned is drawing up policies and expressing opinions, but the essential intermediate link between the "hospital case"—the patient who is ill enough to need removal to an institution—and the institution he is to seek for restoration to health is often forgotten altogether. That link is the ambulance. The sick person of the middle classes sends first of all for his doctor to come to his own house, or visits a neighbouring surgery. By the time he is diagnosed as really ill he is seldom in a fit state to walk or travel by bus to the hospital, and grave harm has been done by dressing a prostrate patient and huddling him into an ill-sprung and draughty taxi for the journey. A smooth running vehicle built for the purpose of conveying the sick is the only suitable way of connecting the patients' home with the hospital. We have had welcome evidence that since we commented some six months ago (*THE LANCET*, 1928, i., 1210) on the need of improvement in the body-work and engine of the type of vehicle used, attention has

Annotations.

"Ne quid nimis."

THE SKELETON OF ERASMUS.

Desiderius Erasmus was born at Rotterdam in 1467, the illegitimate son of a physician's daughter, by Gerard of Tergon, who later became a monk, and the last 15 years of his life were spent at Basle, where he died in 1536. Last June his tomb in the cathedral was opened owing to the construction of a new system of central heating, and on Oct. 19th the bones were restored to their original place. In the interval they were subjected to a close study by Dr. A. Werthemann, of the Pathological Institute of Basle University, and the results were laid before the Basle Society of Natural Sciences at its meeting on Dec. 5th. The circumference of the skull measured 50.5 cm., its capacity 1255 c.cm., corresponding to a brain weight of 1200 g. This weight is small considering that the average weight in Caucasians and Chinese is something over 1300 g. That the man who stands for all time as the supreme type of cultivated common sense applied to human affairs should have had a brain smaller than the average demonstrates once again that quantity of brain substance has not the importance generally attributed to it. From the measurements of the long bones the height of Erasmus during life was calculated at 173 cm., say 5 ft. 8 in. On the left ulnar bone and on the left tibia a thickening was found, parts of which were examined microscopically, and diagnosed as of unquestionably syphilitic origin. The syphilitic disease of Erasmus is of the acquired type; no sign of hereditary syphilis was found. The fact of syphilisation is not in itself very astonishing. Whether or not the disease was introduced into Europe only after the discovery of America—i.e., several years after his birth—there is little doubt that in the lifetime of Erasmus syphilis had the character of a pandemic disease which was carried in many other ways than by clandestine sexual intercourse. Erasmus is credited with a constant fear of infectious diseases, and in his writings he advocated prohibition of marriage for diseased persons. It seems that he recognised the nature of his own condition, for in a letter to his friend Beatus Rhenanus, dated 1518, he described symptoms which can be interpreted as those of syphilis. Dr. Werthemann has no doubt of the identity of the bones after a careful comparison of the skull with the portraits of Erasmus by Holbein.

A SIDELIGHT ON PUBLIC HEALTH IN INDIA.

It occasionally happens that a useful light is thrown on conditions in India by visitors with little or no experience of the country, and Dr. Hoops's report on the League of Nations interchange of health officers¹ which took place in India last December and January is well worth notice. The report emphasises that public health in India is mainly a rural problem, and Dr. Hoops considers that the crux lies in the villages, where, as he says, 90 per cent. of the population live, and where there is at present no settled local organisation to deal with sanitation, water-supply, and elementary medical aid. He justly remarks that the breakdown of the *panchayats* (village councils), which has been one of the results of British administration, has left the rural population worse off in some respects than they were in ancient times, and he evidently thinks that the true interests of the country lie in the revival of these village authorities. This line is, in fact, being explored in the Punjab district of Gurgaon, and the delegates were much interested in an experiment that was being conducted there by an enterprising district officer who has succeeded not only in improving the

agricultural methods and reviving village industries, but also in getting the villagers to clean up their surroundings, to admit light and air to their houses, to improve and regulate their water-supply, and even to undergo inoculation for plague and cholera, when considered desirable, in addition to the customary vaccination for small-pox. Such work is of supreme importance in a country like India, and Dr. Hoops is perhaps not unduly optimistic when he hazards the opinion that if a similar advance could be made in other districts the problem of rural health could be solved in a generation.

At the Calcutta Congress of the Far Eastern Association of Tropical Medicine, which the delegates attended last December, the recent work on kala-azar and the paper of d'Herelle on bacteriophages must have been of exceptional interest to them. Thanks to the labours of Napier, Knowles, R. O. Smith, Acton, Shortt, and others, the diagnosis and treatment of kala-azar have been so much improved that the 90 per cent. mortality which formerly prevailed has been converted into something like 90 per cent. of cures. This has, incidentally, been an excellent example of team-work, the honours being divided between the field workers in Assam and the laboratory and hospital men in Calcutta. With d'Herelle's work on bacteriophages we have recently dealt.² In dysentery and cholera particularly, both from a prophylactic and therapeutic point of view, the results obtained by the discoverer seem very encouraging. The bacteriophage phenomenon is at all events a most interesting biological fact, and if the hopes of d'Herelle are realised the employment of the appropriate bacteriophages in these diseases will mark a very important epoch in tropical medicine. The delegates were struck with the apparent neglect in India of drainage and other measures of mosquito destruction in antimalarial work, and this, it must be admitted, is a weak point. It is, after all, largely a question of funds, but money could hardly be better spent, and larger grants for these purposes would be amply justified by a diminished sick-rate. Attention is drawn in the report to the good effect on the general condition of the people of extensive irrigation works, and the author evidently thinks they more than counterbalance any increase in malaria, even from the public health standpoint. These observations support the contentions of C. A. Gill, who in this province has argued for some years past that the factor of general prosperity and good nutrition is one of the most important considerations in the control of malaria.

As regards general public health organisation in India, the report gives a summary of the present position, but, naturally perhaps under the circumstances, no comment is made. The fact, however, emerges that there is a somewhat excessive tendency towards decentralisation. This, no doubt, is inevitable at the present juncture, but the movement is not without its dangers. Popular government is advancing more rapidly at the periphery than the centre, and it is open to doubt whether an elected provincial council will be as ready to provide funds for purposes of this kind as it should. International considerations—including the Health Organisation of the League of Nations—will bulk more prominently in the future than they have in the past, and the central government will be well advised to maintain a general control, particularly as regards such questions as quarantine, international health legislation, research, and education.

HEREDITARY ANGIOMAS OF THE CEREBELLUM AND RETINA.

RECENT work on cystic hæmangiomas of the cerebellum has brought to light a clinical syndrome that has hitherto received no general or accurate recognition. From a pathological study of two cystic hæmangiomas of the cerebellum Lindau,³ of

³ Lindau, A.: Acta Path. u. Microbiol. Scand., 1926, Suppl. 1.

mental disorders as it might affect general hospitals. The latter is a well-considered scheme for approximating the treatment of early mental illness to that of physical disease; it deals with out-patient clinics, in-patient accommodation, annexes and hostels, and gives valuable advice on the requirements of these "service units." The Council has a great opportunity, now that a large number of poor-law hospitals are likely to be freed from their trammels, of influencing their reorganisation in the right direction. The movement is progressing in the British Dominions, and a scheme is on foot for founding a similar association in India. Another of the Council's activities is the attempt to secure a better place for psychiatry in the medical curriculum, and correspondence to this end has taken place with the General Medical Council.

The Council's aims are well summarised in a sentence in the report: "There is nothing spectacular about the work of the Council, which of its very nature must be slow and to a large extent unnoticed; yet if little by little it can break down the wall of doubt and prejudice which still surrounds mental ailments and can give to the public a knowledge of the resources at its disposal in combating such illnesses, and of the hope which characterises modern methods of treatment, the National Council for Mental Hygiene will have fulfilled an important part of its mission."

The popular course of lectures, which is to be held on Wednesdays during the early months of 1929, includes addresses on Dangerous Ages, Irresistible Impulse, and the Problem of Nervous Breakdown.

ENCEPHALOMYELITIS FOLLOWING MEASLES.

THE rarity of nervous complications of measles has not prevented, in fact has probably favoured, acute controversy as to their nature and origin, few cases having been available for clinical and pathological study. During the first 20 years of the present century only five cases of encephalomyelitis following measles were recorded, though some 20 million children in the British Isles must have contracted measles during that time. Since 1920, however, the incidence has increased, especially abroad, but even so it is rare for any author to have observed more than two cases. In this country a case was recorded by C. R. Box in 1921¹ and by Winnicott and Gibbs in 1926.² Dr. J. G. Greenfield, speaking at the Neurological Section of the Royal Society of Medicine on Dec. 13th, commented on the cases previously recorded and described three which had come under his notice in the spring and early summer of this year. Two of the cases in which he examined the cerebro-spinal fluid were cerebral, one being spinal. No post-mortem examinations were allowed, though only one of the three patients recovered, but in another fatal case he was able to examine the brain. The clinical features in these cases coincided with those described by other observers. The cerebral type is ushered in by a recrudescence of fever, often with convulsions. Delirium, muscular twitchings, and loss of speech are often noticed. But the most constant and characteristic symptom is profound drowsiness or stupor, which is usually associated with neck rigidity, head retraction, or tache cerebrale, and often with rigidity of all the muscles of the body. Kernig's sign is also often present. The convulsions may be so severe and frequent as to lead to the death of the patient, but more often death is directly due to lung complications. The mind gradually clears, and with the return of consciousness a varying degree of damage to the brain may manifest itself in such changes of character and temperament as irritability, tendency to use bad language, and dirty habits. Usually this phase is of quite short duration, a couple of days or a week or two at most. With further recovery there is often

remarkably little evidence of cerebral disturbance, but sometimes there is permanent mental backwardness. The majority of the patients have recovered completely in the course of three or four months. In the spinal type paraplegia with loss of sphincter control is the most characteristic symptom. The paralysis is sometimes of an ascending type, and is often accompanied by sensory loss, either to all forms, or, perhaps more often, to pain and temperature only. The paraplegia of measles thus differs from poliomyelitis in the constancy of severe sphincter paralysis, in the presence of sensory loss, and in the tendency for signs of pyramidal involvement, such as Babinski reflexes and hypertonicity, to appear after the acute phase has passed off. The degree of recovery is remarkable, and usually very little residual paralysis is left behind. In many cases cerebral and spinal symptoms are equally prominent and it is impossible to classify the cases. The abnormalities of the cerebro-spinal fluid are very variable. The pressure is often moderately raised in the cerebral form up to 300 mm., but is little altered in the spinal form. On the other hand, the cell count tends to be higher in the spinal form. As to morbid anatomy, the changes in the nervous system described by Barlow and Penrose were confirmed by Dr. Greenfield in his case. The changes are evenly distributed throughout the cord but are of greater intensity in some regions. In addition to great engorgement of the vessels and some scattered petechial hæmorrhages, many of the vessels are surrounded by a zone of coagulated exudation, and beyond this for a considerable distance the tissues are infiltrated with leucocytes giving the appearance in transverse sections of a series of concentric rings. No changes were found in the nerve cells. This appearance of perivascular softening with cell exudate forming a concentric zone round the vessels has also been found by Siegmund in a case of Brock's and by F. Wohlwill.³ The most characteristic change is the zone of demyelination of greater or less width around many of the small veins. In Wohlwill's cases, however, and in Brock's there was practically no mesodermal reaction, and this variability of mesodermal reaction seems to have led to considerable confusion. The question has been raised whether it is possible to have a form of inflammatory disease of the brain in which there is no evidence of cell exudation, and certain observers have considered that the changes found in the encephalomyelitis of measles are of a purely degenerative character and are not inflammatory. But in view of the acute febrile onset of the nervous complications, the high pressure of cerebro-spinal fluid and papilloedema sometimes present, and the congested and sometimes hæmorrhagic appearance of the brain and cord, Dr. Greenfield finds that the cardinal evidences of inflammation are present.

It seems to him likely, in fact, that cell exudation is caused not by the presence of virus or toxin so much as by the effects they produce on the tissues. The presence of diphtheria toxin or tetanus toxin in the nervous system calls forth no cellular reaction, but far from being absent, it is just their presence in the nervous system which causes the symptoms of paralysis or spasm. Similarly, in demyelinating diseases such as disseminated sclerosis and Schilder's encephalitis there may, or may not, be perivascular infiltration; it is not an essential part of either disease. What is a still more cogent argument is that in post-vaccinal encephalomyelitis, which resembles measles encephalomyelitis very closely, there may be remarkably little evidence of mesodermal reaction, or it may be confined to a very small proportion of the affected vessels. The similarity of the disease to post-vaccinal encephalomyelitis is seen not only in the morbid anatomy, which closely resembles that originally described in the post-vaccinal affection by McIntosh and Turnbull and later by Perdrau. There has been a great increase in the incidence of both

been paid to these points in many districts. The ambulances in the fleet of the Home Ambulance Service of the British Red Cross have always been comfortable and well-sprung. This invaluable servant of the community now has 352 fully-equipped motor vehicles at various stations scattered throughout the country, and the new Register, just published,¹ gives their locations in alphabetical order, and the address and telephone number of the officer in charge. It is a reference book that every country practitioner should possess. Its foreword outlines the history of the movement from the end of the war, when a large number of the Society's ambulances were still able to answer the roll call and be handed over to civilian needs. The British Red Cross Society and the Order of St. John of Jerusalem wisely decided that the call for united service did not cease with the war, and seized this opportunity to organise a fleet of rural ambulances. The vehicles are staffed by well-trained volunteers who are willing to leave their trade or business by day or by night at the call of the sufferer needing transport. Moreover, all collecting, organising, and responsibility connected with the upkeep is carried out by voluntary effort, so that the Society is able to charge a fee within the means of the patient, and to transport for nothing those who cannot afford to pay at all. A football match, a carnival, a procession, would all seem incomplete without its blue-uniformed ambulance men, but few people remember, as the familiar figures pass by, that these are shopkeepers, miners, clerks, and professional men who accept no material reward for their loss of business or leisure or for the hours they spend in initial and renewed training.

The need increases every day, and the report for the quarter ending Sept. 30th last shows that 2852 road accident cases alone were carried in the ambulances, the total number of patients moved being 705,219. The Joint Council can now state that the country is so thoroughly equipped that every part of it can be reached within a reasonable time. It is a reproach to the counties that it should go on to say that there is as yet no universal appreciation of the extent of the support that can be obtained from the public if they are approached systematically. The county areas are given great latitude in organisation and they ought to be very nearly self-supporting. Those that have not yet found out how to do it will be wise if they get their arrangements on a satisfactory basis before the increasing demand for transport of middle-class patients to hospital tempts some commercial concern to snatch from them the fees of their less impoverished clients, and thus prevent them from helping those who cannot afford to pay.

MALPIGHI.

LONDON has had many medical centenaries to celebrate this year, but it would have been a grave omission if she had failed to remember with honour the "father of microscopy," for Marcellus Malpighi had a close connexion with our own Royal Society. The tercentenary of his birth at Crevalcore, near Bologna, on March 3rd, 1628, was celebrated at the Royal Society of Medicine, under the auspices of the Historical Section, on Dec. 12th. The Royal Society had loaned a portrait in oils as well as a splendid collection of drawings from his pen, and other items from the Royal Society of Medicine's own collection and from the Wellcome Historical Medical Museum made up an exhibit fit to form the text of a memorial address from Prof. Giuseppe Franchini of Bologna. Malpighi's work was encyclopedic; he was an able legatee of the wonderful heritage left to him and his contemporaries by the revival of scientific learning and the discovery of the microscope. He investigated the development of the chick and described the formation of many of its organs; he studied the anatomy of plants and was familiar with their cellular structure and stomata; he gave accurate accounts of the germination of many seeds; he

discovered the organs of taste and touch, and he published illuminating works on the internal organs of man. One of his most striking pieces of work was on the silkworm, and this he dedicated to the Royal Society, by which it was printed. He is memorable for completing the work of Harvey by his discovery under the microscope of the capillary vessels linking the arterial and venous systems. Perhaps of all his work, that on the brain was the most interesting, for he transformed it from a spongy secreting gland into a complex organ made up of little grey and white bundles. He believed, however, that the cortex was glandular and described the grey matter as hanging on the white bundles "like dates on a palm." He is commemorated in the nomenclature of the histological structure of the kidney, which he described—among others organs—in a treatise published in 1666 and entitled "*De viscerum structura exercitatio epistolica*." Malpighi had the receptive mind which so strongly marked John Hunter, Louis Pasteur, and other eager investigators. He idly plucked a branch from a chestnut tree and immediately the vascular bundles caught his eye, and the end of that was "*The Anatomy of Plants*." His description of the circulation in the gills of the tench was the outcome of another casual event. He was inexhaustible in the pursuit of knowledge, and was an exquisite draughtsman. If he failed it was in interpretation, and indeed some of the structures he depicted quite clearly have had to wait until modern times for their explanation. The work forms a curious link between the old days and the new; his microscopical research links him to our own times, yet Malpighi, as Prof. Franchini reminded his audience, lived in the days when lessons on anatomy had to be held in private houses on mouldering scraps of corpses snatched from funerals or rescued from new-dug graves at the risk of attack from relatives, guardian monks, vultures, or hungry dogs. His contemporary and friend, Bellini, was stoned by the students of Pisa, and hay and straw were hurled at the professors of Paris. Malpighi did not escape, for his colleagues incited his students against him, even to threatening his life. He was a mild and prudent man and greeted opposition with silence and magnanimity. Fortunately he lived to see his fame acknowledged; a monument was erected to him by the people of Bologna in the university building. Later the monuments, memorials, and medals in his honour became legion, and Prof. Franchini was able to show more than two dozen photographs of these indications of popular admiration. Malpighi married Francesca, the daughter of Massani, in whose house, while still a student, he had joined a "*corus anatomicus*" for dissection and discussion. She died a few days before him, thereby accelerating his end. From pains in his head he prophesied quite correctly his death from an apoplectic stroke which took place at the age of 66. An autopsy on his body was made by Baglivi, and only this year Prof. Franchini opened his coffin to investigate what remained of the great microscopist. All but the large bones and the vault of the skull had turned to dust.

MENTAL HYGIENE.

If civilisation is to be preserved from the ill-effects of increasing stress, the care of the mind must become part of the training of every citizen. No organisation works more energetically towards this end than the National Council for Mental Hygiene, which completed its fifth successful year of existence last week. Its chief concern during the year was propaganda. Several local representatives have been appointed and a considerable number of meetings have been held, at which educative lectures have been delivered; a large public meeting is contemplated and a course of popular lectures on mental hygiene is to be given at the rooms of the Medical Society of London. The Council has become affiliated with the National Council of Women of Great Britain. Its report contains two valuable memoranda as appendices, one on child guidance and the other on the early treatment of

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXXXVII.—THE TREATMENT OF ACUTE HÆMATOGENOUS OSTEOMYELITIS.

BACTERIA may gain access to a bone directly through an external wound as in a compound fracture, or from a nearby focus in the soft parts; or indirectly through the blood stream from a distant primary focus (hæmatogenous osteomyelitis).

Acute hæmatogenous osteomyelitis is mainly an affection of youth, with its greatest incidence in the male sex between the ages of 2 and 15. The disease has become comparatively uncommon in recent years. The primary source of infection may be (a) in the skin—e.g., an abrasion, a crop of boils, or, in infants, umbilical sepsis; or (b) in the upper respiratory tract—e.g., tonsils, teeth, or sinuses. In not less than 75 per cent. of cases the responsible organism is the *Staphylococcus pyogenes aureus*. The streptococcus is found in about 10 per cent. of cases, and more rarely organisms such as the pneumococcus or *Bacillus coli* are isolated in pure culture.

Site.—The blood-borne infection is usually arrested in one of the long bones—the upper end of the tibia, lower end of the femur, lower end of the tibia, and upper end of the humerus being the sites of election. The flat bones are less frequently involved, but pelvic osteomyelitis is seen from time to time. In grave infections multiple foci may develop. Injury may play an important part in localising the lesion to a particular region.

Origin and Spread of Osteomyelitis.

In the *growing bone* the osteomyelitic lesion almost invariably begins in the cancellous tissue beneath the epiphyseal disc (metaphysis), a region where the end artery system and the sluggish blood stream favour the lodgment of infective emboli. From the tiny juxta-epiphyseal focus, spread may occur in various directions, but occasionally the lesion remains encysted for some days or even weeks. The earliest and most important line of spread is directly towards the surface. The pus having reached the subperiosteal space, tracks downwards along the shaft owing to the ease with which the periosteum strips. Longitudinal spread in the interior of the bone along the cancellous lining, and in the medullary canal itself, is a much later event. It is not unusual to find the whole shaft denuded, with the medullary canal still uninvaded. The attachment of the periosteum to the epiphyseal line presents a stout barrier to invasion of the neighbouring joint. In a minority of cases the infection reaches a long bone by the nutrient artery, and the initial focus develops towards the middle of the shaft (*diaphysis*). Spread then occurs in the interior of the bone in a proximal and distal direction.

In the *adult long bone* osteomyelitis may originate (a) in the middle of the shaft, or (b) in the cancellous tissue at the end of the shaft. In the method of extension certain differences are noted. When pus has reached the surface, the periosteum, which does not strip as easily as in the child, often gives way and allows widespread tracking of an abscess in the intermuscular planes. Occasionally the initial lesion becomes shut off by a zone of sclerosis with the ultimate formation of a chronic bone abscess—Brodie's abscess.

Reaction of Bone to Infection.—As the osteomyelitis spreads, its effects on the host bone are both destructive and stimulative. Destruction is signified by the amount of necrosis. But necrosis in the early stage does not necessarily imply the future separation of sequestra, for devascularised areas of cortex or cancellous bone may be integrated later in the shaft, as the infection becomes attenuated. This is part of the process of natural repair. The stimulative action of infection is well exemplified in the construction of the new case or involucrum under the periosteum, a bony shell which may ultimately house fully matured sequestra. Such extensive sequestra are seen only in neglected cases when the infection has spread far beyond the limits of the original juxta-epiphyseal focus.

Symptomatology.

In many cases there is a *prodromal phase* before the typical clinical picture is established. This insidious mode of onset may last from seven days to two or

three weeks, and is more usual in older children or adolescents. Important symptoms are a vague feeling of "seediness," intermittent limp, fixed pain at the end of a long bone, and on local examination metaphyseal tenderness. This clinical stage corresponds to the stage in which the juxta-epiphyseal focus has not reached the surface, and it is at this stage that diagnosis should often be possible. In other patients, especially in infants and young children, the prodromal phase is fleeting or unrecognisable, and the local and general symptoms are ushered in abruptly.

In the *early stage* the general symptoms are those of an acute infection, mild, severe, or fulminating in type. A rigor may occur at the onset, and the temperature often rises to 103° or 104° F. The fixed pain and the metaphyseal tenderness become more insistent, and now actual bony swelling is recognisable. The latter sign indicates that the infection has reached the subperiosteal space.

Later considerable swelling with oedema and redness of the skin may be present, and where rupture of the periosteum has occurred the fluctuation of an abscess may be detected. A moderate effusion into the neighbouring joint is not uncommon, but the joint movements remain free and painless. In fulminating osteomyelitis the clinical picture of acute septicæmia may overshadow the local signs, and in exceptional cases death may take place in two or three days from the onset. In the average case with severe toxæmia a blood count will usually show a marked leucocytosis, and a culture may demonstrate the presence of the staphylococcus or streptococcus. The symptoms of a systemic infection usually abate when the pus escapes from tension, either spontaneously or after surgical drainage.

Diagnosis.

Since the diagnosis of acute osteomyelitis is rarely made in the early stage, the mortality of the disease is far too high. Mistakes continually arise because the clinical syndrome bears a superficial resemblance to certain acute infective conditions. The more important of these are as follows:—

(a) *Acute Rheumatism.*—It is doubtful whether acute monarticular rheumatism exists at all as a clinical entity in childhood. Even if the possibility of such a disease be admitted, joint pain, joint tenderness, and muscular spasm present a very different picture from a painful, tender, thickened metaphysis. Such distinctions are appreciable if the affected region be carefully palpated.

(b) *Acute Cellulitis.*—In this condition there is early swelling and induration of the soft parts, skin redness, and the complete absence of localised metaphyseal tenderness and bony thickening.

(c) *Acute Infective Arthritis.*—In superficial joints, such as the knee or elbow, there is rarely the slightest difficulty in diagnosis. The differentiation between acute suppurative arthritis of the hip and acute osteomyelitis of the neck of the femur, is, however, a more difficult problem. In both conditions early exploration is demanded.

Special difficulties arise in the diagnosis of acute osteomyelitis of the deeper bones—for example, the pelvis—where the local signs may be masked. For this and other reasons pelvic osteomyelitis has an exceptionally high mortality. Suggestive signs of involvement of the pelvis are (a) referred pain in the lower limbs; (b) pelvic tenderness on rectal examination; (c) deep tenderness over the affected bone—e.g., between the iliac crest and the great trochanter, over the ischial tuberosity, or the pubis.

A radiographic examination only rarely affords information of value in the early stages. Occasionally where a juxta-epiphyseal focus has remained latent for some weeks a localised area of destruction may be visible in the radiogram.

In all doubtful cases exploratory puncture of the bone should be performed without delay. A small incision should be made down to the metaphysis, the periosteum incised, and the cortex drilled in several places. If pus appears appropriate drainage should be established. If no pus is found the material extruded from the drill holes should be sent for bacteriological culture, and the wound closed with

diseases during recent years; in both diseases also there is a definite delay of the onset of nervous symptoms till after the acute phase of the initial disease has passed off, and the time interval from vaccination or measles rash to encephalitis is remarkably constant. In Dr. Greenfield's opinion these facts confirm the suggestion that the virus which causes the encephalitis is not the same as that causing the exanthem, but is a special neurotropic virus which is stimulated to activity by the exanthematous disease. It is impossible to say, without further evidence, that the encephalomyelitis of measles is identical with post-vaccinal encephalomyelitis, but in the cases examined no clinical or pathological differentiation is possible. The relationship, if any, of these conditions to the other demyelinating diseases (disseminated sclerosis, diffuse myelitis, or Devic's disease, and Schilder's encephalitis) is also still unknown. In any case it seems to be established, both on clinical and on pathological grounds, that the typical lesion of the encephalomyelitis of measles is not a "haemorrhagic encephalitis," but one of the diffuse perivascular demyelinating diseases closely related to post-vaccinal encephalomyelitis.

INTERNATIONAL HYGIENE.

THE Office International d'Hygiène Publique held its autumn session at Paris towards the end of last October, when a variety of epidemiological questions were discussed. We are indebted to Dr. Abt, the new director of the Office, for a short summary of the proceedings in advance of the elaborate procès-verbaux which will appear later in the *Bulletin Mensuel*. It is of interest that a permanent committee has now been formed, consisting of delegates of countries interested in the sanitary control of the Mecca Pilgrimage, to examine all information regarding that control each year, and to make recommendations for the better coördination of the work undertaken by the different administrations for this purpose under the terms of the International Sanitary Convention of 1926. Another forward move is the proposal to issue a comprehensive annual, giving data regarding quarantine administration in all countries. The committee of the Office has begun giving authoritative opinions on such administrative questions as the abolition of unnecessary consular visas on bills of health and deratisation certificates, the use of wireless telegraphy for quarantine purposes, the necessity of rat guards, and cognate matters. Air traffic, too, is raising new problems in the dissemination of disease, and the Office has decided to study the basis on which measures of sanitary defence should be insisted upon in the case of aircraft arriving from infected countries. The discussion at the session revealed the apprehension as to the spread of yellow fever in Africa which led to the Anglo-French Conference at Dakar in April, and a more recent agreement between the Belgian Congo and Angola for the application of special local measures in addition to those advocated by the International Sanitary Convention.

PRESENTATION TO PROF. PRIESTLEY SMITH.

A PLEASANT little ceremony took place at the Queen's Hospital, Birmingham, on Friday evening last week, when Prof. Priestley Smith was presented with his portrait in appreciation of his long association with the hospital. It was in 1867 that Joseph Priestley Smith first entered the Queen's Hospital as a medical student, after having been apprenticed, as befitted his prænomen, for four years at mechanical engineering. He thus came to his medical studies with a working knowledge of mechanics and familiar with the properties of materials, an equipment which provided the necessary background to his ophthalmological work and made it feasible for his name to become attached to all manner of appliances

used in the oculist's consulting-room. Seven years after taking his qualification Priestley Smith gained the Jacksonian prize for his essay on glaucoma, and his theory of the development of that mysterious and disastrous disease still holds the field. In 1898 he delivered the Bowman lecture of the Ophthalmological Society. In 1901 he was elected F.R.C.S., joining the small group of members of 20 years' standing who have been so honoured, and in 1901, when the Nettleship gold medal was to be awarded for the first time, it was Priestley Smith who was the recipient. Finally, the American Ophthalmological Society last year gave him the Lucien Howe medal in succession to Kohle and Fuchs, after sending over a representative to see for himself the apparatus used to investigate circulation in the eye. Sir Charles Hyde, President of the Queen's Hospital, who made the presentation, remarked on the bewildering nature of Priestley Smith's achievements, which read to him like a fairy story, and, he added, "like the fairies, he does not appear to grow older." Apart from his work on glaucoma and the growth of the crystalline lens, Priestley Smith will always be associated with the study of visual function by means of perimetry, and with the educative treatment of strabismus; a tape for measuring the angle of squint and various perimeters appear in every instrument maker's catalogue. The portrait has been painted by that well-known artist and technician, Mr. Harold Speed, and is considered excellent both as a likeness and as a picture; it includes some accessories suggestive of research work. In replying to the presentation Prof. Priestley Smith asked the chairman of the hospital to accept the portrait which is to be hung in the board room.

THE Royal College of Physicians of London will be closed from Saturday, Dec. 22nd, till Saturday, Dec. 29th, both days inclusive.

THE Medical Society of London has arranged a specially interesting programme for the second half of the present session. Beginning with a pathological evening on Jan. 14th, it continues on Jan. 28th with a discussion, introduced by Dr. E. I. Spriggs, on Starvation in Treatment. On Feb. 28th Prof. A. H. Burgess and Mr. C. H. S. Frankau will open a discussion on Acute Intestinal Obstruction, and on March 11th Dr. Reginald Miller and Dr. W. G. Wyllie will speak on the Chronic Dyspepsias of Children over the Age of Infancy. At a meeting on March 25th the subject will be the Medical Indications for the Induction of Abortion and Premature Labour, the openers being Mr. Eardley Holland, Dr. B. T. Parsons-Smith, and Dr. Bernard Hart, and the session will close with the annual meeting on May 13th, when Prof. Grey Turner will deliver the annual oration, taking Cancer of the Colon as his subject. The Society's Lettsomian lectures on Dermatology in Relation to other Branches of Medicine will be given by Dr. H. W. Barber on Feb. 18th and 27th, and March 6th, and the annual dinner will take place at the Trocadero Restaurant on Friday, March 8th.

The President of the French Republic has appointed Dr. David Thomas Barry, F.R.C.S., professor of physiology at University College, Cork, to be a Knight (Chevalier) of the Legion of Honour.

KING GEORGE V. HOSPITAL.—The Lord Mayor of London and the Chairman of the London County Council have issued a combined appeal for the erection of the proposed King George V. Hospital at Ilford, which is to serve the large new population of Becontree and the neighbourhood around Ilford. Some 200,000 persons are to be housed, mainly by the London County Council, and it is expected that eventually the population will approach half a million. At present the only hospital accommodation is the Ilford Emergency Hospital of 70 beds. Both the King and Queen have given subscriptions.

phenomenon. However, one phenomenon of asthma and the other so-called allergic diseases—e.g., hay-fever, paroxysmal rhinorrhœa, angioneurotic œdema, urticaria, and so forth—occurs which differs from that seen in experimental anaphylaxis. A preliminary sensitising injection of antigen is always necessary to produce experimental anaphylaxis, whereas in naturally occurring allergic diseases evidence of such a preliminary sensitisation is usually wanting. This is not always so, because it is possible that the antigen—of which only quite small doses are necessary—may get in through an abraded mucous membrane. For instance, during gastro-intestinal disturbances it is possible that some undigested product such as egg protein may be absorbed from the intestinal tract and so give rise to a permanent state of hypersensitiveness or anaphylaxis to this substance. However, in allergy there are no doubt other factors also present, and heredity or diathesis, nervous factors, and occasionally exposure to light or drugs undoubtedly play a part in addition to the protein irritation and the original trauma through which the protein gained access to the body.

A Clinic for Allergic Diseases.

Shortly after the war an out-patient clinic for allergic diseases was instituted at the Royal Victoria Hospital, Montreal; it is now a recognised part of the out-patient service of the hospital. Thirty or forty different substances are used in this clinic for testing purposes. They include common foodstuffs, animal emanations, or epidermal proteins and pollens. Both the last two groups cause attacks of asthma by being inhaled, and even foodstuffs occasionally produce their effect by inhalation, as in bakers and housewives exposed to the dust of wheat and other grain. Orris root, the rhizome of the iris lily, is a common constituent of scented and tinted face powders because of its agreeable odour and flesh tint and is a potent cause of asthma and paroxysmal rhinorrhœa, due to inhalation. House dust and van Leeuwen's atmospheric mould allergens are other possible causes. In Montreal the tests are carried out by putting on the skin of the forearm a drop of N/10 or N/20 solution of NaOH and dissolving in this a small quantity of the protein applied on the point of a small knife; a superficial cut one-eighth of an inch long is then made through the mixture. A positive result appears in 20–30 minutes, and consists of an urticarial wheal half a centimetre in diameter with a surrounding zone of erythema. Results even less pronounced than this are recorded since they may point to the ætiological factor. The control must, of course, be completely negative.

Out of 160 cases of asthma which do not include patients suffering from hay-fever, vasomotor rhinitis or skin diseases, 25 have been classified as asthmatic bronchitis. Here the chronic bronchitis is the primary disturbance, and has been present for some time. The condition is not really allergic at all. These patients are worse in winter. There is much breathlessness on exercise. They do not enjoy intervals free from bronchitis between the attacks. There is much cough, leading to severe dyspnoea, often described as choking fits, and the sputum is copious. Potassium iodide and stramonium are given with codeine if the cough is distressing; not infrequently a change of climate is necessary. The remaining 135 cases of the series were classified as true asthma, and only 16 per cent. of these were found to be negative on skin testing. The sensitive patients fell into two groups—those mainly sensitive to epidermal substances, and those mainly sensitive to food, but there is frequent overlapping between the groups in individual cases. In the epidermal group feathers were positive in 58 per cent., cat hair in 38 per cent., horse dander in 36 per cent., and dog hair in 26 per cent., and other epidermals such as sheep's wool, rabbit hair, and cattle hair in 18 per cent. Seldom did a patient react to but one of these animal emanations; usually a group relationship to be distinguished from true multiple sensitisation was found to exist. Of other inhaled proteins orris root reacted in 9 per cent. and pollen in 29 per cent.; of the foods, wheat reacted in 10 per cent., oats in

13 per cent., rice in 10 per cent., barley in 9 per cent., corn in 4 per cent., and rye in 3 per cent. In vegetables the following was the order of frequency: tomatoes 15 per cent., potatoes 12 per cent., celery 12 per cent., beans 10 per cent., peas 8 per cent. Of animal and fish foods, lactalbumin was found to lead to reaction in 12 and casein in 3 per cent.; egg-yolk in 4 and egg-white in 3 per cent.; pork in 3; beef and chicken each in 2 per cent.; while of fish proteins haddock, mackerel, and salmon each reacted in 4 per cent.

In examining patients at this clinic the personal history is especially directed to finding out how the different tissues of the body are affected during the attack: whether, for example, the symptoms are: (a) ocular—history of swelling, itching, or lachrymation; (b) nasal—sneezing, blockage of the nose, itching, profuse watery discharge, the so-called vasomotor rhinitis syndrome; (c) pharyngeal—itching of the soft palate, cough; (d) bronchial—tightness, wheezing, paroxysmal cough, and clear sputum; (e) cutaneous—manifestations such as urticaria, angioneurotic œdema, eczema, erythema, and pruritus; (f) gastro-intestinal—idiosyncrasies to certain foods, attacks of vomiting, pain, and diarrhœa, otherwise unexplained; (g) urinary; and (h) nervous. As has been emphasised frequently the family history in allergic disease is of the greatest importance. In the series discussed this was positive in but 32 per cent. of cases, but the figure is lower than it would have been had it been possible to make more careful inquiry. In the records of other observers roughly 50 per cent. of patients have given a positive family history. Treatment consists in keeping the patient away from those substances which produce the most marked skin reactions. In feather cases kapoc pillows are prescribed, though it must be remembered that kapoc, or some mould that it harbours, occasionally produces asthma. In epidermal cases, where association with animals is essential, vaccination is recommended.

Infective and Reflex Asthma.

In a group of cases classified as infective and reflex asthma usually no bronchitis is present between the attacks; but there is evidence that the asthma is due to infection in other parts of the body. The question remains open whether the asthma is due to sensitisation to the bacterial proteins or is merely due to reflex irritation. That such reflex asthma may be due to marked deviation of the septum, septal ridges or spurs, and marked turbinate hypertrophy is quite easy to understand. Brodie and Dixon proved definitely that the stimulation of the nasal mucous membrane produces a reflex bronchial constriction.

Thirteen cases of asthma were associated with antral infection, and in only two or three were proteins found definitely positive. In all these cases the symptoms occurred chiefly in the winter, in wet weather, and especially at night time on lying down, so that the asthma may have been due to irritation from the trickling of a nasal discharge down the pharynx.

Seven cases were associated with nasal polypi alone, two others with ethmoiditis in addition, and three with chronic ethmoiditis, making a total of 12 cases. Of eight cases in whom polypi were removed, the result was good in five, but in each of these there was a definite protein factor which was also attended to. In three patients negative to proteins, but suffering from bronchitis, there was no appreciable change.

Ten cases had such mechanical defects as marked septal deviation, septal ridges or spurs, and pronounced hypertrophy of turbinates, all tending to obstruct the airway and to favour infection. In all but two protein sensitisation was found. In only one was operation resorted to, and it was successful. Tonsils and adenoids do, in a small number of cases, play an important rôle, though the usual history is that these have been operated upon at least once without relief. However, after other avenues have been explored, operation may be called for.

In some patients asthma starts or is associated with "colds in the head": here no cause is demonstrable.

a superficial drain. If the diagnosis of osteomyelitis is not confirmed, no harm can result from such a procedure in competent hands. Its more frequent application would mean the saving of many limbs and lives.

The Management of the Case.

The treatment of osteomyelitis is based on two aims: (1) to combat the systemic infection by suitable general and specific therapy; and (2) to establish adequate drainage of the infected area at the earliest moment.

1. *General Measures.*—It is unnecessary to describe the ordinary treatment of an acute infective illness. Of the results obtained from such methods as immuno-transfusion, intravenous antiseptic medication—e.g., glauramine or mercurochrome—reports are conflicting. But in desperate cases the potential value of such measures can hardly be ignored.

2. *Operative Measures.*—All drainage operations should be designed to avoid (a) further devascularisation of bone; and (b) the introduction of infection into non-infected areas. Three types of drainage operation are available.

(a) *Subperiosteal and Metaphyseal Drainage.*—At first the infected area consists of the original juxta-epiphyseal focus alone. A little later the subperiosteal collection of pus must be drained in addition. The metaphysis should be opened freely by multiple drill holes, or by the removal of a small trephine disc. All pus and debris should be sponged out lightly, but no curetting of the cancellous tissue should be practised. At this stage there is no justification for the common practice of extending the opening in the bone along the shaft, and exposing the medullary canal for a distance equivalent to the area of the subperiosteal stripping (the "gutter" operation).

(b) *Diaphyseal Drainage ("Gutter" Operation).*—At a later stage when the whole of the shaft is infected free drainage of the interior demands an adequate opening into the medullary cavity. The "gutter" operation, which is now unavoidable, is apt to imperil the viability of the remainder of the shaft, and in a subcutaneous bone has the further disadvantage of leaving an avascular adherent scar.

(c) *Primary Subperiosteal Resection of the Diaphysis.*—This operation, which has been advocated in the early stages of acute osteomyelitis, has not found favour with the majority of surgeons. The advantages claimed are (a) that it gives a most adequate drainage of the subperiosteal space; (b) that all infected bone likely to die at a later stage is removed in the beginning; and (c) prolonged suppuration and the need for secondary operations are avoided. Such advantages are mainly theoretical. The outstanding objection to subperiosteal resection is the risk of failure of regeneration and consequent interference with the growth of the limb. The procedure is irrational in the metaphyseal stage of the infection, but in a long bone riddled with osteomyelitis it may occasionally be considered as an alternative to the "gutter" operation in the subacute stage.

HARRY PLATT, M.D. Manch., M.S. Lond.,
F.R.C.S. Eng.,

Senior Hon. Surgeon and Surgeon in Charge, Orthopaedic Service, Ancoats Hospital; Clinical Lecturer in Orthopaedics, University of Manchester.

THE BIRMINGHAM HOSPITALS.—The scheme for the creation of a new hospital centre to be associated with Birmingham University has advanced a step further by the appointment last week of a secretary to the executive board. The appointment, the salary of which is £1500 a year, has been conferred upon Captain J. E. Stone, chief accountant of St. Thomas's Hospital, secretary of the Central Bureau of Hospital Information, and author of various books on hospital organisation and management. The new hospital, which is to contain 750 beds, is estimated to cost £750,000.—The Birmingham Hospitals Contributory Scheme now has 323,000 workpeople members employed by over 4215 firms in and around Birmingham. This is an increase of 66,000 in the first year. Of the 4215 firms, ever, only 1458 have yet joined.

ASTHMA AND RELATED DISEASES.

DR. A. T. HENDERSON'S REVIEW OF RECENT WORK.*

IN 1902 Charles Richet found that if a dog which had received a non-toxic dose of some poisonous protein was after a certain time given a second injection of the same protein, a violent and often fatal reaction followed. To this phenomenon was given the name of anaphylaxis. It is a curious feature of anaphylactic shock that its symptoms vary in different animals, though collapse to a greater or less degree and fall of body temperature always occur. In the guinea-pig, for example, violent respiratory efforts are made and the smooth muscles of the bronchioles are in extreme contraction. In the rabbit respirations are increased in a different way and death is due to right-sided heart failure, the result of increased resistance in the pulmonary circuit due to constriction of the pulmonary arterioles. In the dog the liver becomes greatly engorged. Dale and his co-workers drew attention to the great similarity between these reactions and those due to poisoning the animals by histamine; this suggested that the sudden breakdown of protein molecules is the factor directly responsible for anaphylactic shock, and it has now been definitely established that the cause is the interaction of antigen and antibodies in the tissue cells of the animal. The injection of antigen in the first place leads to the production of antibodies, which remain for a time in the circulating blood. In this early stage the animal is immune; further injections of antigen do it no harm since the antigen is taken up by the antibodies in the blood stream. But after 15–18 hours the antibodies leave the circulation and enter the tissues. In this later stage the animal is anaphylactic. This is proved by making an animal anaphylactic to horse serum, removing its uterus, washing it free from blood, and treating it with horse serum. A maximal contraction is obtained; but the uterus does not contract if other sera are used instead of horse serum. The reaction is thus specific. From what has been said it follows that though the animal shortly after an injection of antigen is not anaphylactic, its blood as soon as it contains antibodies is potentially anaphylactic; if this blood is injected into a second animal the latter becomes passively anaphylactic (or passively sensitised) 15–18 hours later, when the injected antibody reaches the tissue cells. Further, it has been found that the antibody disappears from the blood as the animal becomes passively anaphylactic. Active immunity is produced by treating an animal with successive doses of antigen at frequent short intervals so that the blood becomes crowded with antibodies. Such an animal will not suffer from anaphylactic shock if a fresh dose of antigen is administered because there are sufficient antibodies in the blood to neutralise the antigen, although it may be proved that the tissues themselves also contain antibodies. This method is used when a patient with hay-fever is treated with small but gradually increasing doses of pollen, so that when he is subjected to a large dose in the hay-fever season no attack follows.

There is another method of arresting anaphylaxis when it is once established. It is to give the animal a non-fatal anaphylactic shock which automatically gets rid of the antibodies from the tissues so that a refractory period of some duration follows before the antibodies again become stored there. This refractory state has been called anti-anaphylaxis.

The response of the guinea-pig to anaphylactic shock resembles so closely an attack of asthma in man as to suggest to anyone that asthma is an anaphylactic

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1927 statistics of eight metropolitan boroughs:—

Name of borough and estimated (R.-G.) population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart diseases.	Infant and neonatal mortality.	Marriages, &c., under 2 years.	Maternal mortality from childbirth.
Kensington (176,700)	13.0	13.8	0.80	1.83	3.1	2.4	66.23	10.9	2.2
Paddington (142,700)	15.5	13.6	0.82	1.73	2.6	2.2	79.23	7.2	4.1
Lambeth (307,500)	16.2	12.6	1.0	1.66	2.5	1.7	55.22	5.8	4.2
Bermondsey (121,000)	18.5	12.9	1.45	1.35	3.0	1.6	67.—	5.4	4.0
Battersea (162,000)	16.6	12.2	1.03	1.49	2.3	2.4	53.28	2.5	2.1
Bethnal Green (117,000)	19.9	11.3	1.12	1.29	2.5	2.1	58.20	10.2	1.7
Westminster (136,500)	10.0	12.3	0.83	1.73	2.8	2.4	69.34	11.4	5.7
Holborn (42,200)	12.0	12.5	1.30	1.18	3.1	1.9	38.8	10.0	4.0

The young (1-5) child death-rates per 1000 births were: Kensington 32, Paddington 30, Lambeth 34, Bermondsey 42, Battersea 29, Bethnal Green 37, Westminster 23, Holborn 24. — = No information.

Kensington.

Dr. James Fenton calls particular attention to the statistics with regard to tuberculosis. Since 1919, when the death-rate was 1.31, there has been a steady decline in the tuberculosis mortality to its 1927 rate of 0.80. Soon after the war the council assumed full control of tuberculosis work in the borough. Dr. A. W. K. Picard is the whole-time clinical tuberculosis officer. The borough is divided into seven areas with a woman health officer in charge of each, and it is estimated that the seven women health officers devote three-sixteenths of their time to tuberculosis work. The dispensary staff also includes two indoor nurses, a clerk, and a caretaker. At St. Mary Abbots Hospital there are 48 beds for emergency cases, some of whom are waiting for sanatorium treatment, for advanced cases with unsatisfactory home conditions, and for patients who cannot be adequately nursed at home. Dr. Picard acts as visiting medical officer to the hospital for these patients and arranges for their transfer as required to the L.C.C. Sanatoria. X ray diagnosis and light treatment is available and the consulting services of the staff of St. Mary Abbots. The tuberculosis dispensary is used fairly extensively as a consultation centre. Thus 251 cases were referred to the dispensary by private practitioners during 1927. Every effort is made to secure the examination of all contacts and there is a steady rise year by year in the number of contacts examined. Suspects are also keenly followed up. A dental officer is provided and home nursing is carried out by the Kensington District Nursing Association. There is an active case committee embracing representatives of all statutory and voluntary bodies likely to be interested, and one of its latest ventures is the provision of a handcrafts class for tuberculous patients.

Interesting details are given of the municipal scheme for the control of acute rheumatism. From Oct. 1st, 1927, acute rheumatism in children under 16 defined as (a) rheumatic pains or arthritis if accompanied by a rise of temperature, (b) rheumatic chorea, and (c) rheumatic carditis was made a notifiable

disease for a period of three years. The rheumatism supervisory centre is established at the Princess Louise Hospital under the charge of Dr. R. C. Lightwood (assistant physician to the hospital), who becomes consulting physician to the borough of Kensington for acute rheumatism. Beds are provided for acute rheumatism both at St. Mary Abbots and the Princess Louise Hospital, under the charge of Dr. Lightwood. The council make an annual grant towards the provision of beds in suitable recovery homes. After notification the staff of the medical officer of health make full inquiries as to the conditions in the home and persuade the parents to take the child to the supervisory centre. A committee, including representatives of all the statutory and voluntary bodies likely to be interested, supervises the scheme and helps in the searching out of cases needing attention. "Long stay" cases for convalescent treatment may be dealt with by the M.A.B. hospitals or arranged for through voluntary channels. During the first three months of the operation of the scheme 48 cases were notified, the homes of which were investigated by the health visitors. The centre was opened in temporary premises on Oct. 29th and transferred to the new Princess Louise Hospital on Dec. 3rd. Up to the end of the year nine sessions had been held at which 26 new patients presented themselves. On May 21st, 1928, the Princess Louise Kensington Hospital for Children was opened by the King and Queen, and then consisted of an out-patient department and two ward units providing 36 beds, with accommodation for the staff.

Antenatal work makes good progress in Kensington. There are eight municipal clinics and in addition a special antenatal clinic at Queen Charlotte's Hospital Nurses' Home. It is considered that about 60 per cent. of the expectant working-class women in the borough now receive antenatal advice. The maternal mortality for 1927 was encouraging.

Paddington.

The report of Dr. G. E. Oates shows that the public health services have developed on somewhat different lines to those of its neighbour Kensington. Thus, there are two tuberculosis dispensaries, both of which are voluntary agencies subsidised by the council. The dispensary at St. Mary's Hospital serves the eastern portion and the Paddington Tuberculosis Dispensary (20, Talbot-road) serves the western portion of the borough. In addition to the subsidies the council pays for dental treatment by arrangement with the British Dental Hospital and for the cost of artificial pneumothorax at 10s. 6d. per refill. During 1927 four patients received the latter treatment at a cost of £24 13s. 6d. There is ample hospital accommodation for both mother and baby when needed for ophthalmia neonatorum. Out of 15 cases of ophthalmia notified in 1927, eight were treated as in-patients. Cases of puerperal fever are removed to one or other of the M.A.B. hospitals. Seven cases were notified in 1927 and all were nursed in hospital. In addition, 31 cases of puerperal pyrexia were notified, 26 of which received in-patient treatment. Mr. A. W. Bourne, F.R.C.S., has been appointed consultant for puerperal pyrexia but no request was made for his assistance during the year.

The maternity and child welfare centres are provided by the Paddington School for Mothers and carry out some antenatal work. During 1927 283 women from Paddington were admitted for confinement to Queen Charlotte's Hospital and most of these attended the antenatal department of the hospital.

Paddington was the first area in Great Britain to make acute rheumatism a notifiable disease (from March 1st, 1927). The regulations "enjoin the medical officer of health to make such inquiries and take such steps as are necessary or desirable for investigating the source of disease, for removing conditions harmful to the patient, and arranging for the treatment of the patient." "All these inquiries and any necessary

other than an apparent lack of resistance in the nasal mucous membrane. These patients are always worse in the winter months, or rather in the late autumn and early spring, when the weather is most capricious, and the changes sudden and disturbing. Lastly, a large group of patients, who are true asthmatics, have a superadded infection of the bronchial tubes. Twenty of these exhibited multiple sensitisation to a marked degree. Nearly all had had asthma for a long time. Usually, in this group, vaccines are of material benefit.

MEDICINE AND THE LAW.

Injury from Rat-bite.

Two years ago an infant about a week old was bitten by a rat in the Crayford Maternity and Nursing Home in Kent. An action in respect of the infant's injury was recently brought against the trustees of the home, the committee of management, and the nurse in charge of the baby at the time. On the third day of the trial it was apparently conceded that no action would lie against the trustees, but the rest of the claim was left to the jury, who disagreed and were discharged. The form of the action was a claim by the infant (through its father) for damages for personal injuries due to the defendants' negligence, a claim by the mother for damages for personal injuries to herself caused by shock, and a further claim by the father for special damage incurred by reason of the injuries to his wife and child. The actual facts about the rat-bite were not much disputed. The plaintiffs' case was that, in accordance with the usual practice at the home, the baby was taken from its mother at 9 P.M. and placed in a cot in the basement kitchen of which the floor was some 3 ft. below the ground level. At 1.30 in the morning the nurse on night duty heard a child cry, and, on going to the cot, saw a rat emerge and disappear through the window. The baby's face had been bitten. At 6 A.M. the mother was awakened and told that her baby had met with an accident; to save her feelings she was told the accident was caused by a cat. The mother said that, when she saw the baby's disfigured face, she received such a shock to her nerves that she was ill for a long time; she still suffered from bad dreams about rats. The father said that twice, when motoring, his wife had fainted at the sight of rats running across the road. The issue in the case was whether the rat-bite was a mere accident which, however regrettable, did not create any legal liability, or whether the defendants had been guilty of negligence. The actual allegation of negligence put forward by the plaintiffs was the failure to protect the child's cot in a place which was known to be infested with rats. There was, however, a good deal of evidence to the effect that no rats had ever been seen on the premises at any other time, and that there had never been any complaint of rats being present. The house was an old one, but the drains were in perfect order and there were no signs of rat-holes in the room. The sanitary inspector and rat officer for the local district council said he had examined the house and grounds and found no trace of rats there. The matron at the home explained that one reason why the babies were placed in this kitchen at night was that there was a good fire there and that prematurely born infants required heat and care all night, and it was impossible to have them in the wards with their mothers. She said no patient and no member of the domestic staff had ever mentioned rats to her. No meal was cooked in the kitchen after 12.30 P.M. and no food was kept there. It appeared from the evidence of another witness that, since this accident, the babies at the home are still placed in cots in the kitchen under charge of a nurse at night, but no longer in a basement kitchen. The jury, as already stated, was unable to agree upon a verdict either in favour of plaintiffs or defendants. This means that the plaintiffs are free to start their action all over again.

Parent's Neglect of Child.

Reference was made in these notes a few weeks ago to summary proceedings taken at the instance of the Wolverhampton Education Committee against a father under Section 12 of the Children Act for neglect of his child in refusing to allow an operation for the removal of tonsil obstruction. The father's contention was that he had not refused medical treatment, but he would not allow an operation which might have a fatal result. The magistrates were prepared to convict him, but adjourned the case to see what course he would take. He has now applied for a further adjournment to enable him to call medical evidence—presumably to show that the suggested operation is dangerous and that the child's health is either in no need of treatment or can be improved by some other method than an operation. The medical evidence for the prosecution at the original hearing was unanimous and unchallenged and was such as has hitherto been accepted in similar proceedings under Section 12. It will be interesting to see the result of the adjournment; the court originally adjourned, it was understood, to see whether the father would do voluntarily what the court had power to compel—not to enable him to reopen his defence.

Fumes from Electrical Power Station.

A farmer at Barton-on-Irwell brought an action at Manchester Assizes against the Manchester Corporation, praying for an injunction to restrain the corporation from so working their electricity station as to commit a nuisance by emitting fumes heavily charged with sulphur and sulphur compounds. The fumes, he said, were injurious both to the land which he occupied and to his own comfort and health. The corporation admitted the nuisance, but pleaded that the power station was one of a kind authorised by Parliament to be built at the place in question and that no means which science could suggest could have avoided the nuisance. Mr. Justice Talbot upheld the contention of the corporation and dismissed the plaintiff's action, but on appeal (by a majority of two judges to one) the Court of Appeal has reversed the decision. The case, which is of supreme importance to the undertakers of electrical power stations and to local residents, is likely to go to the House of Lords, though the Court of Appeal in granting the injunction has suspended its order for a year to enable the corporation to adopt measures to mitigate or end the annoyance of which the plaintiff complained. In delivering the majority judgment Lord Justice Scrutton said the corporation did not seem, in building its station which was to be worked on a larger scale than any in England, to have considered what would be the effect of discharging so great a volume of sulphur fumes upon the countryside. They had not since consulted any outside chemical or electrical expert to ascertain whether the nuisance could not be abated or terminated by a different construction of the works or chimneys or by restricting the work of the station. No similar damage was reported in any other case and the corporation had been unable to explain why its works alone had caused such a nuisance. The corporation might be able to prove that it was inevitable that a generating station must damage agricultural land by depositing sulphur thereon, but they had not established that fact, nor had they satisfied the court that all possible means had been taken to discover the cause and the remedy and to adopt reasonable precautions against causing a nuisance.

SUNDERLAND MENTAL HOSPITAL.—It is proposed to enlarge this hospital at a cost of £150,000. The existing buildings are intended to hold 300 patients but there are at present more than 70 beyond that number, and nearly 50 others have had to be sent elsewhere. It is suggested by the Board of Control that the new institution should also serve South Shields and Hartlepool, thus avoiding the necessity for providing separate hospitals for those places.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are 1927 statistics of eight metropolitan boroughs:—

Name of borough and estimated (R.G.) population.	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.

The dispensary staff also includes two indoor nurses, a clerk, and a caretaker. At St. Mary Abbots Hospital there are 48 beds for emergency cases, some of whom are waiting for sanatorium treatment, for advanced cases with unsatisfactory home conditions, and for patients who cannot be adequately nursed at home. Dr. Picard acts as visiting medical officer to the hospital for these patients and arranges for their transfer as required to the L.C.C. Sanatoria. X ray diagnosis and light treatment is available and the consulting services of the staff of St. Mary Abbots. The tuberculosis dispensary is used fairly extensively as a consultation centre. Thus 231 cases were referred to the dispensary by private practitioners during 1927. Every effort is made to secure the examination of all contacts and there is a steady rise year by year in the number of contacts examined. Suspects are also keenly followed up. A dental officer is provided and home nursing is carried out by the Kensington District Nursing Association. There is an active case committee embracing representatives of all statutory and voluntary bodies likely to be interested, and one of its latest ventures is the provision of a handicrafts class for tuberculous patients.

Interesting details are given of the municipal scheme for the control of acute rheumatism. From Oct. 1st, 1927, acute rheumatism in children under 16 defined as (a) rheumatic pains or arthritis if accompanied by a rise of temperature, (b) rheumatic chorea, and (c) rheumatic carditis was made a notifiable

disease for a period of three years. The rheumatism supervisory centre is established at the Princess Louise Hospital under the charge of Dr. R. C. Lightwood (assistant physician to the hospital), who becomes consulting physician to the borough of Kensington for acute rheumatism. Beds are provided for acute rheumatism both at St. Mary Abbots and the Princess Louise Hospital, under the charge of Dr. Lightwood. The council make an annual grant towards the provision of beds in suitable recovery homes. After notification the staff of the medical officer of health make full inquiries as to the conditions in the home and persuade the parents to take the child to the supervisory centre. A committee, including representatives of all the statutory and voluntary bodies likely to be interested, supervises the scheme and helps in the searching out of cases needing attention. "Long stay" cases for convalescent treatment may be dealt with by the M.A.B. hospitals or arranged for through voluntary channels. During the first three months of the operation of the scheme 48 cases were notified, the homes of which were investigated by the health visitors. The centre was opened in temporary premises on Oct. 29th and transferred to the new Princess Louise Hospital on Dec. 3rd. Up to the end of the year nine sessions had been held at which 26 new patients presented themselves. On May 21st, 1928, the Princess Louise Kensington Hospital for Children was opened by the King and Queen, and then consisted of an out-patient department and two ward units providing 36 beds, with accommodation for the staff.

Antenatal work makes good progress in Kensington. There are eight municipal clinics and in addition a special antenatal clinic at Queen Charlotte's Hospital Nurses' Home. It is considered that about 60 per cent. of the expectant working-class women in the borough now receive antenatal advice. The maternal mortality for 1927 was encouraging.

Paddington.

The report of Dr. G. E. Oates shows that the public health services have developed on somewhat different lines to those of its neighbour Kensington. Thus, there are two tuberculosis dispensaries, both of which are voluntary agencies subsidised by the council. The dispensary at St. Mary's Hospital serves the eastern portion and the Paddington Tuberculosis Dispensary (20, Talbot-road) serves the western portion of the borough. In addition to the subsidies the council pays for dental treatment by arrangement with the British Dental Hospital and for the cost of artificial pneumothorax at 10s. 6d. per refill. During 1927 four patients received the latter treatment at a cost of £24 13s. 6d. There is ample hospital accommodation for both mother and baby when needed for ophthalmia neonatorum. Out of 15 cases of ophthalmia notified in 1927, eight were treated as in-patients. Cases of puerperal fever are removed to one or other of the M.A.B. hospitals. Seven cases were notified in 1927 and all were nursed in hospital. In addition, 34 cases of puerperal pyrexia were notified, 26 of which received in-patient treatment. Mr. A. W. Bourne, F.R.C.S., has been appointed consultant for puerperal pyrexia but no request was made for his assistance during the year.

The maternity and child welfare centres are provided by the Paddington School for Mothers and carry out some antenatal work. During 1927 283 women from Paddington were admitted for confinement to Queen Charlotte's Hospital and most of these attended the antenatal department of the hospital.

Paddington was the first area in Great Britain to make acute rheumatism a notifiable disease (from March 1st, 1927). The regulations "enjoin the medical officer of health to make such inquiries and take such steps as are necessary or desirable for investigating the source of disease, for removing conditions harmful to the patient, and arranging for the treatment of the patient." "All these inquiries and any necessary

other than an apparent lack of resistance in the nasal mucous membrane. These patients are always worse in the winter months, or rather in the late autumn and early spring, when the weather is most capricious, and the changes sudden and disturbing. Lastly, a large group of patients, who are true asthmatics, have a superadded infection of the bronchial tubes. Twenty of these exhibited multiple sensitisation to a marked degree. Nearly all had had asthma for a long time. Usually, in this group, vaccines are of material benefit.

MEDICINE AND THE LAW.

Injury from Rat-bite.

Two years ago an infant about a week old was bitten by a rat in the Crayford Maternity and Nursing Home in Kent. An action in respect of the infant's injury was recently brought against the trustees of the home, the committee of management, and the nurse in charge of the baby at the time. On the third day of the trial it was apparently conceded that no action would lie against the trustees, but the rest of the claim was left to the jury, who disagreed and were discharged. The form of the action was a claim by the infant (through its father) for damages for personal injuries due to the defendants' negligence, a claim by the mother for damages for personal injuries to herself caused by shock, and a further claim by the father for special damage incurred by reason of the injuries to his wife and child. The actual facts about the rat-bite were not much disputed. The plaintiffs' case was that, in accordance with the usual practice at the home, the baby was taken from its mother at 9 P.M. and placed in a cot in the basement kitchen of which the floor was some 3 ft. below the ground level. At 1.30 in the morning the nurse on night duty heard a child cry, and, on going to the cot, saw a rat emerge and disappear through the window. The baby's face had been bitten. At 6 A.M. the mother was awakened and told that her baby had met with an accident; to save her feelings she was told the accident was caused by a cat. The mother said that, when she saw the baby's disfigured face, she received such a shock to her nerves that she was ill for a long time; she still suffered from bad dreams about rats. The father said that twice, when motoring, his wife had fainted at the sight of rats running across the road. The issue in the case was whether the rat-bite was a mere accident which, however regrettable, did not create any legal liability, or whether the defendants had been guilty of negligence. The actual allegation of negligence put forward by the plaintiffs was the failure to protect the child's cot in a place which was known to be infested with rats. There was, however, a good deal of evidence to the effect that no rats had ever been seen on the premises at any other time, and that there had never been any complaint of rats being present. The house was an old one, but the drains were in perfect order and there were no signs of rat-holes in the room. The sanitary inspector and rat officer for the local district council said he had examined the house and grounds and found no trace of rats there. The matron at the home explained that one reason why the babies were placed in this kitchen at night was that there was a good fire there and that prematurely born infants required heat and care all night, and it was impossible to have them in the wards with their mothers. She said no patient and no member of the domestic staff had ever mentioned rats to her. No meal was cooked in the kitchen after 12.30 P.M. and no food was kept there. It appeared from the evidence of another witness that, since this accident, the babies at the home are still placed in cots in the kitchen under charge of a nurse at night, but no longer in a basement kitchen. The jury, as already stated, was unable to agree upon a verdict either in favour of plaintiffs or defendants. This means that the plaintiffs are free to start their action all over again.

Parent's Neglect of Child.

Reference was made in these notes a few weeks ago to summary proceedings taken at the instance of the Wolverhampton Education Committee against a father under Section 12 of the Children Act for neglect of his child in refusing to allow an operation for the removal of tonsil obstruction. The father's contention was that he had not refused medical treatment, but he would not allow an operation which might have a fatal result. The magistrates were prepared to convict him, but adjourned the case to see what course he would take. He has now applied for a further adjournment to enable him to call medical evidence—presumably to show that the suggested operation is dangerous and that the child's health is either in no need of treatment or can be improved by some other method than an operation. The medical evidence for the prosecution at the original hearing was unanimous and unchallenged and was such as has hitherto been accepted in similar proceedings under Section 12. It will be interesting to see the result of the adjournment; the court originally adjourned, it was understood, to see whether the father would do voluntarily what the court had power to compel—to enable him to reopen his defence.

Fumes from Electrical Power Station.

A farmer at Barton-on-Irwell brought an action at Manchester Assizes against the Manchester Corporation, praying for an injunction to restrain the corporation from so working their electricity station as to commit a nuisance by emitting fumes heavily charged with sulphur and sulphur compounds. The fumes, he said, were injurious both to the land which he occupied and to his own comfort and health. The corporation admitted the nuisance, but pleaded that the power station was one of a kind authorised by Parliament to be built at the place in question and that no means which science could suggest could have avoided the nuisance. Mr. Justice Talbot upheld the contention of the corporation and dismissed the plaintiff's action, but on appeal (by a majority of two judges to one) the Court of Appeal has reversed the decision. The case, which is of supreme importance to the undertakers of electrical power stations and to local residents, is likely to go to the House of Lords, though the Court of Appeal in granting the injunction has suspended its order for a year to enable the corporation to adopt measures to mitigate or end the annoyance of which the plaintiff complained. In delivering the majority judgment Lord Justice Scrutton said the corporation did not seem, in building its station which was to be worked on a larger scale than any in England, to have considered what would be the effect of discharging so great a volume of sulphur fumes upon the countryside. They had not since consulted any outside chemical or electrical expert to ascertain whether the nuisance could not be abated or terminated by a different construction of the works or chimneys or by restricting the work of the station. No similar damage was reported in any other case and the corporation had been unable to explain why its works alone had caused such a nuisance. The corporation might be able to prove that it was inevitable that a generating station must damage agricultural land by depositing sulphur thereon, but they had not established that fact, nor had they satisfied the court that all possible means had been taken to discover the cause and the remedy and to adopt reasonable precautions against causing a nuisance.

SUNDERLAND MENTAL HOSPITAL.—It is proposed to enlarge this hospital at a cost of £150,000. The existing buildings are intended to hold 300 patients but there are at present more than 70 beyond that number, and nearly 50 others have had to be sent elsewhere. It is suggested by the Board of Control that the new institution should also serve South Shields and Hartlepool, thus averting the necessity for providing separate hospitals for these places.

Keith thinks it is impossible to dissociate the marked improvement in maternity and infant statistics from the progressive policy of the Council. The chief centre is a well-equipped building with provision for light treatment, dental treatment, and massage. There is a staff of ten health visitors and nine part-time women doctors. Dr. Ruth C. Townsend reports on the maternity clinic at which a special session for postnatal cases has just been provided. Dr. Helen M. Mackay conducts a special consultation clinic, of which artificial light treatment is a feature, and which receives its cases from all the other clinics. The joint tuberculosis dispensary for Hackney and Bethnal Green is at the City of London Hospital for Diseases of the Heart and Lungs. The tuberculosis officer, Dr. H. Tylford Howell, is not greatly impressed with the benefits of artificial sunlight. He would also like to see the L.C.C. provide more beds for advanced cases in lieu of the scheme for the removal of the children of such patients from their homes. It is difficult to get the consent of the parents to this "boarding out."

Westminster.

Dr. Andrew J. Shinnie describes housing as second to none in importance among the public health issues, and expresses the opinion that the proposed schemes of his council will go a very long way to solving the problems of overcrowding, illegally occupied separate basement dwellings, and other insanitary conditions associated with housing shortage. The block of buildings named "Admiral House" was expected to be occupied in the middle of the present year and to house 234 persons in 11 two-roomed, 25 three-roomed, and 5 four-roomed dwellings. Westminster have also arranged to accept 50 houses on the L.C.C. estate at Hammersmith. The city council nominated 70 tenants but 15 were refused by the L.C.C. on financial grounds and 15 withdrew their applications. At the end of the year 40 Westminster tenants were housed on this estate. House-to-house inspection is being pursued with great activity. Dr. Shinnie has a good deal to say in criticism of the amateur survey which was made of Victoria ward in May to which great publicity was given and which has entailed much inspection without corresponding benefit. The kato-thermometer has been used for testing the ventilation of workshops, and the results seem to indicate that further investigation will be needed before the principles suggested by Prof. Hill can be brought into practical application. Immunisation was begun towards the end of 1926, and at the end of 1927 270 children had been treated without any unpleasant reactions. It was noteworthy that 30 of the children brought up for voluntary immunisation against diphtheria had evaded compulsory vaccination.

Holborn.

Dr. C. W. Hutt considers that "antidiphtheria immunisation is worthy of an extensive trial." Since it was begun in Holborn 720 persons have been immunised, all except 12 under the age of 15. Retesting, although unpopular with parents, is found to be necessary as 68 out of 555 immunised were found to be still Schick-positive, and six confirmed cases of diphtheria occurred among children, who had received the routine three injections but had not been retested. The first of the six, aged 4 years 4 months, when first Schick-tested had a severe attack 13 months after the last injections; the second, aged 6 years 5 months, a very mild attack 13 months after; the third, aged 3 years 3 months, a mild attack 18 months after; the fourth, aged 6 years 8 months, a severe attack 22 days after; the fifth, aged 7 years, a mild attack two days after; and the sixth, aged 1 year 8 months, a mild attack four years after. The fourth and fifth cases, of course, occurred before the lapse of the period required to secure immunisation. The reaction after the injections was in practically every case negligible. In order to facilitate antenatal supervision the borough council has, with the approval of the Ministry, adopted from Jan. 1st, 1928,

voluntary notification of pregnancy by medical practitioners and midwives for which fees of 2s. 6d. in private practice and 1s. in public practice will be paid. The notifications will only be made with the approval of the expectant mothers.

Leicestershire.

LEICESTERSHIRE is now among the progressive authorities establishing orthopaedic schemes. Dr. J. S. Fairer reports that a very substantial advance is being made by the provision of beds in Mansfield Orthopaedic Hospital. For children living in the northern area of the county facilities are available at St. Gerards' Hospital, Coleshill; patients are selected at the clinics of the Loughborough Cripples' Guild by Mr. S. A. Malkin, who is surgeon both to the hospital and to the Guild. Children from the southern part of the county are referred to the orthopaedic clinic at the Leicester Royal Infirmary, where they are selected for in-patient treatment by Mr. R. S. Lawson. For areas inaccessible to these larger centres it is proposed to establish clinics under the school authority for the provision of massage and electrical treatment; such a clinic is now being started at Coalville. It is recognised that local clinics will make for economy since by their use good results can be obtained with a shorter stay in hospital. The necessity of these facilities was made particularly obvious by the epidemic of anterior poliomyelitis of 1926, the effects of which were brought out in a special survey made in 1927 of the physically defective school-children in the county. Three beds are reserved for infants under the care of the maternity and child welfare committee in the Mansfield Hospital. The co-ordination of the infant welfare work with school and other branches of public health is made easy by the fact that the county medical officer is ultimately responsible for them all and by the fact that the senior medical officer for welfare work is also the clinical tuberculosis officer, while the other two medical officers are also school doctors. The transfer of relevant information between various departments is thus easy. Dr. Mary Weston has conducted an inquiry on the origin of infantile defects in school entrants and especially on the influence of measles and whooping-cough; the outcome was that the percentage of defectives (36 per cent.) was not materially affected by either or both these diseases. An analysis of the figures for special defects did not substantially modify these results, which are rather unexpected. The figures on which they are based are admittedly small (1000 children), but the inquiry was evidently conducted on sound lines. It may be that wider general knowledge and more efficient treatment during the course of these illnesses has resulted in a diminution of serious sequelae.

County of Warwick.

The county of Warwick includes some large urban districts, so that the medical staff has to deal with

action," says Dr. Oates, "have been delegated to the Rheumatism Supervisory Centre which was opened at Paddington Green Children's Hospital on Oct. 9th, 1926." "The Centre is under the personal supervision of one of the honorary physicians to the hospital and there is also a salaried medical officer, who devotes her whole time to visiting cases of the disease and making such inquiries as may elucidate the causes thereof." There were 38 notifications received during the year and 27 of these children attended the supervisory centre.

Commenting on the high infant mortality, Dr. Oates suggests that Paddington is too much built over and too overcrowded, and that many families who are not badly off have to share with other families dwelling-houses which were only built for one family. There is a lack of garden and yard space. There are no slums in the ordinary sense and the number of houses, which require closing and demolition, is small. It is difficult to find any area in the borough suitable for housing development, and no municipal houses were erected during the year. The 1924 arrangement with the L.C.C., by which Paddington is allocated 15 houses per 1000 of those built by the County Council, still holds, but the estates mainly available, Becontree and Downham, are too far away. The waiting list of tenants is well over 1000.

Lambeth.

Dr. Joseph Priestley presents his farewell report after 32 years' service. He did not live long to enjoy the leisure of retirement, as will be seen from the obituary notice on another page. In June, 1895, Dr. Priestley was appointed medical officer of health to the old parish of St. Mary's, Lambeth, which became the borough of Lambeth in 1901. The report takes the opportunity of reviewing the many changes which have taken place in the public health service during that period and contrasts the death-rates of 1895, 1901, and of recent years. Among institutions he specially mentions the Council's new maternity home at Knight's Hill, which had a fine record for 1927 and will shortly need extension to cope with the requirements of the borough. A new assessment committee has been appointed to deal with the fees to be paid by the mothers. The report gives Dr. Priestley's opinion alone as to further needs and does not commit his successor (Dr. A. G. G. Thompson) who took over the duties on Nov. 1st, 1927. Two of these needs given by Dr. Priestley are the appointment of a woman medical officer for the detailed work of maternity and child welfare and the provision of an up-to-date central tuberculosis dispensary. At the present time there is an entirely inadequate central dispensary in Brixton with a branch dispensary at St. Thomas's Hospital, and the proposal has been put forward that the needs of the borough might be met by the establishment of a second dispensary at King's College Hospital. This would, in Dr. Priestley's opinion, be a great mistake and amount to a delegation of the whole of the council's tuberculosis work to outside organisations. An important advance made during the year was the new appointment of an experienced bacteriologist, Miss F. M. Speakman, to carry out the work in the municipal laboratory.

Bermondsey.

Dr. R. King Brown, in his valedictory report after 28 years' service, gives an interesting account of the development of the local public health services. Among post-war schemes he mentions the establishment in 1920 of a municipal dental surgery, under the direction of a (whole-time) surgeon, Mr. Grantley Smith. During 1927 a branch was opened in charge of a part-time dental surgeon. The new cases treated during 1927 exceeded 3000 and included pre-school children, children of school age, expectant and nursing mothers, and tuberculosis cases. Since July, 1924, as the result of a lecture at Guy's Hospital by Dr. Rollier, Bermondsey Council has reserved six beds at Leylin for the "long-stay" treatment of advanced

non-pulmonary tuberculosis. During that time 14 patients have been sent and Dr. D. M. Connan, the tuberculosis officer (who has now succeeded Dr. King Brown), reports favourably as to the permanency of the cures effected at Leylin. Dr. Connan's report on the work of the specially built solarium, which is equipped for giving outdoor light treatment, shows that 456 new patients were treated. The rickets and malnutrition children under 5 did well when they attended regularly. The health of some ten antenatal cases was greatly improved. The value of light treatment for surgical tuberculosis, if given cautiously over a considerable period, was indubitable, but no definite pronouncement was possible as to pulmonary tuberculosis.

Details are given of the census taken during the year to obtain reliable data as to overcrowding. There are in the borough 29,284 families. Of these, 19,887 lived under conditions which give one person or less to a room; 6634 had two persons to a room; and 2763 families lived under conditions which give three persons or more to a room. One area of four acres has been cleared by the borough council, one of six acres is being cleared by the County Council, and the clearance of another area is in contemplation. Much of the work of the Bermondsey residents is of a casual nature and connected with the waterside. Such workers must be housed near their work. Dr. Brown urges that, in letting municipal houses, more care should be taken to see that the accommodation is exactly suited to the needs of the family, so as to avoid waste of rooms on the one hand and the evils of overcrowding and subletting on the other.

Battersea.

Dr. G. Quin Lennane reports that the development of antenatal work during the past four or five years has no doubt contributed to the satisfactory improvement in the maternal and infant mortalities and that the increased attendances at the central clinic at the borough maternity hospital will shortly render it necessary to increase the accommodation by the erection of an out-patient block. Miss Alice Bloomfield, F.R.C.S., who conducts four antenatal sessions weekly, shows that 1140 patients attended, being an increase of 68 over the previous year. The maternity hospital has 30 beds and admitted 602 cases. The appointment of a resident medical officer, who has also assisted at the antenatal clinics, has been a great advantage in securing continuity of treatment. At one of the clinics 674 women were tested by the Wassermann reaction, of whom 12 reacted. Of the babies born to the latter, six had a negative Wassermann, four appeared to be healthy but did not come up for testing, and two had a positive Wassermann, probably owing to the fact that they came under treatment too late. Half of them came after the seventh month. Dr. Lennane reports that "serious and even dangerous overcrowding" exists in the lower wards of the borough, and hopes that steps will be taken to speed up the provision of dwellings at rentals within the reach of those whose need is greatest. In October a clinic was established at one of the centres for the immunisation of children against diphtheria, under the charge of Dr. Mabel Brodie, and 52 children were being immunised at the close of the year.

Bethnal Green.

Dr. F. Leonard Keith, who took over the duties on May 2nd, in his first annual report picks out housing as the most serious single factor adverse to the public health. In 1919 13 unhealthy areas were scheduled by his predecessor, Dr. Oates. Only two of these areas have been attacked as yet, one by the borough and the other by the County Council. The borough council has fully exercised its powers considering its limitations. Procedure with respect to individual houses is precluded by common sense and humanity in the absence of alternative accommodation, and the housing problem is complicated by the prevalence of unemployment and low wages. Dr.

in the building which was formerly the Hillsfoot Training School of the Delinquency Board, and next year a similar school for boys will be provided. The children in this group are in practice divided into: (a) those requiring an extended period of residence outside the city with special medical attention; and (b) those who require a shorter period under good conditions but without special medical attention. There is now accommodation for both types, the Hillsfoot School receiving 70 Protestant girls of type (b).

The balance of treatment and inspection has been disturbed by the industrial dispute which, by affecting the financial position of many families, caused an increased demand for treatment and consequently a restriction of the time available for medical inspection, so that the number of routine inspections was lower than last year. The number of cases of ear diseases shows a rise of over 20 per cent. The attendances for treatment in general show small increases, but that for ionisation is much higher, indicating the value which is now placed on this treatment. Eye diseases show an increase of 37 per cent., especially in conjunctivitis due to decided epidemics in May and the early summer and in autumn. Affections of the skin in general account for nearly 14,000 cases as against 12,300 last year; impetigo accounts for 1000 of the increase, while scabies has had an increased prevalence for the first time since 1920. Dr. Roberts says that in previous years there has been a tendency for the actual diseases of the skin to decrease and for injuries, abscesses, and burns to increase. This year the accident type of case is six times as common as it was in 1920, but the usual fall in diseases of the skin has been prevented by the industrial conditions. Ringworm, however, has yielded to the influence of the special skin school and X ray treatment to such an extent that the special school has been closed. Necessitous cases of illness, for whom emulsion and drugs were given free, have been nearly 30 per cent. more numerous than last year. Many more teeth were treated this year. In this matter the greater enlightenment of the parents might be held responsible, but it is noteworthy that increase is in extractions and not in fillings.

MENTAL HOSPITAL REPORTS.

THE *Derby Borough Mental Hospital* had 479 patients on its registers at the end of the year, meaning that there were only 17 vacant beds. The recovery-rate was 22.7 per cent. and the death-rate 6.4 per cent. The cause of death, verified by autopsy in 29 instances, was heart disease in nine patients—the commonest cause. There was no zymotic disease or influenza and only seven patients were under treatment for tuberculosis. The medical superintendent ascribes these satisfactory results to the improved diet and the high standard of nursing. Parole was granted to 40 patients and weekly shopping parties of 30 women go out beyond the estate. A cinema is to be installed and a convalescent hospital and laboratory are needed; at present a small room is set aside for routine pathological investigations. Six nurses obtained their certificate during the year, one with distinction. The committee has also 44 defectives under certificate in various institutions throughout the country. A house is being adapted to form a home for 13 low-grade able-bodied defective girls.

The *Wills County Mental Hospital* housed 1146 patients at the end of last year, 30 fewer than at the beginning. The recovery-rate was 26.9 per cent. and all but two of those discharged had a probationary period on trial, 18 with money allowances. The death-rate was 9.6 per cent., a large figure almost wholly accounted for by deaths of aged people: the next commonest causes were tuberculosis, heart disease, and general paralysis. The cause was verified by autopsy in 75.6 per cent. of cases. There was no epidemic, but there were 16 cases of dysentery, six fatal, and two cases of erysipelas. The visiting com-

missioners urge the provision of a laboratory and ultra-violet ray apparatus. A sister tutor has been appointed and ten nurses obtained their certificate during the year. The two out-patient clinics at Swindon and Trowbridge have already justified their existence; 35 patients have attended the former and 31 the latter.

The *Roxburgh, Berwick, and Selkirk District Asylum* had 363 patients on May 15th, 1928. The recovery-rate for the year was 23.9 per cent., and this low figure and the high death-rate of 13.4 per cent. is ascribed to the large number of aged patients admitted. No less than 42 per cent. of the admissions for the last two years have been senile cases, many almost moribund. Autopsies were held on 25 cases. There was no serious epidemic. Two visiting dental surgeons have attended fortnightly. A cinema has been installed. There are also 57 defectives under the care of the Board. Eleven nurses obtained their certificate during the year, and the number of certificated nurses would be larger but that many leave to obtain a general nursing training—a step which cannot be deplored, although it deprives the institution of valuable service.

MINISTRY OF HEALTH.

ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER.

(Concluded from p. 1165.)

TUBERCULOSIS.

THE number of fresh cases of tuberculosis coming to the knowledge of the health authorities during 1927, whether by formal notification under the Tuberculosis Regulations or from other sources, was 77,890. Notification is, on the whole, more effectively carried out year by year, but the reports of medical officers of health show that many deaths from tuberculosis have occurred amongst cases not previously notified. The number of deaths registered from all forms of tuberculosis in England and Wales for 1927 was 38,173. In England, on April 1st, 1928, tuberculosis work was being carried out in 440 dispensaries, and, in addition, 95 other premises were approved for special forms of treatment, including orthopaedic out-patient care of tuberculous cripples after return from residential treatment. There were 378 approved tuberculosis officers. The number of beds allocated to tuberculosis in institutions, excluding 108 institutions concerning which no information is available, is 22,618. The number of patients occupying these beds varies: a certain proportion is always unoccupied particularly in the winter months. On April 1st, 1928, there were 19,710 patients, including 6128 children in the 22,618 beds.

In surveying the question as to how the tuberculosis scheme is working throughout the country, Sir George Newman passes under review problems of notification, diagnosis, bacteriological examinations of sputum, the use of X rays, home visitation, and length of sanatorium treatment. The figures given relating to residential treatment should be studied closely by those anxious to use the available bed accommodation to its utmost. The Ministry suggested in Circular 280 the advisability of differentiating patients into the early, intermediate, and advanced stages. They proposed that early cases or others in which there is hope of definite arrest of disease should be retained for long periods, also advanced cases admitted to institutions because they were dangerously infective; but that the needs of the intermediate class would usually be met by short periods of treatment, repeated when necessary. Yet in some areas a considerable proportion of the intermediate cases were retained in sanatoria for prolonged periods—over six months. The intermittent character of the disease makes it fairly certain that many patients in this class will relapse in any case. It

secondary schools and the continuation school at Rugby. The area is likely to undergo further changes, for by the Act that came into force on April 1st, 2550 school-children were transferred from the authority of the county to that of the extended city of Coventry. The change will mean some adjustment of the nursing staff and two of the clinics for minor ailments will no longer be required. The curtailment of the area may be of advantage, since the present strength of the health visiting staff is only barely sufficient for the ordinary routine work. As a result of an endeavour to economise on the expenditure on operations for tonsils and adenoids, an appeal was made to the medical inspectors to lower their standards and so reduce the number of cases referred for treatment. Accordingly, only 3.9 per cent. of all children have been referred for operation as compared with 6.7 per cent. last year. Such a marked decrease seems scarcely sound; it is not justifiable to allow children to suffer from all the physical and mental handicaps and the economic depreciation caused by obstructions of the nasal passages for a small saving in expenditure. But in many parts of the country there seems to be a tendency to be more conservative in recommending operative treatment, and the decrease may be due to causes other than the desire to economise. Considerable progress has been made in the development of the orthopaedic scheme and most of the county is now covered, but it is held up at Stratford-on-Avon and in the Tamworth district until sufficient funds are forthcoming from the county council. Dr. Hamilton Wood includes in his report a valuable account written by Mr. R. P. Marsh of his work of organising physical education in all its branches. This account appropriately follows the section on orthopaedics, for in this county there is a real unity of all the work designed to promote the right development of the child, from orthopaedic surgery, remedial and physical exercises, to activities like swimming and organised games.

Northumberland.

Arrangements for the care of children in the counties with scattered populations are often less advanced than those in urban districts. Northumberland has still no orthopaedic scheme, efforts to promote one having been frustrated by inability to secure hospital accommodation. One step, however, has been taken in the appointment of an orthopaedic surgeon, Mr. William Mackenzie, and it is hoped that before long some workable plan may be presented. The scheme for the operative treatment of tonsils and adenoids is likely to be considerably extended in the near future. Dr. W. Whitley notes that the incidence of tonsils and adenoids appears to have fallen by 50 per cent. since 1920, and he thinks the fall may be partly due to change of standard; if that be so it is the more important that all those who are recommended for treatment should obtain it. The proposal to appoint a second dentist was not carried out for lack of suitable premises. It is now suggested that a dental van would be of value and would carry treatment into otherwise inaccessible places. Reports from other counties similarly placed, such as Cumberland where this device has been tried, show that it has proved very useful. The dental surgeon, Miss C. M. Anderson, deplores the prevalence of dental caries in infants; there is a general lack of oral hygiene and the children are neither trained nor interested in care of the mouth and teeth. That ignorance rather than apathy is the obstacle is shown by the fact that children who have been previously treated and inspected usually maintain better oral hygiene than the rest. Miss M. Wardle, organiser of physical training, writes of the importance of good posture and its important bearing on good health and hygiene. There are no special schools belonging to the local authority in Northumberland, and many defective children of all kinds still attend elementary schools or receive no education of any

Colchester.

The report of Dr. W. F. Corfield shows that steady progress is being made. The actual number of routine inspections has fallen by 200; this is partly due to the decrease in the number of children reaching the age for medical inspection (which is more or less general over the country), and partly to an accidental local factor, the reduction in the number of children in two schools owing to an outbreak of measles and also to the illness of a school nurse. Of the orthopaedic clinic Dr. Corfield says that the good work done has been far greater than he expected, and that every year a larger number of children who would have grown up with a deformity such as a club-foot are now discovered in time, and if they are not completely cured the deformity is so modified and moulded that a limb which would have been unsightly and almost useless is made strong and useful. The orthopaedic surgeon, Mr. Whitchurch Howell, sees also infants referred from the infant welfare department, and it is hoped that next year he will have the assistance of a nurse trained to give remedial exercises. A testimonial to the work done in Colchester is the large and increasing percentage of parents attending medical inspections; in 1925 it was 77, in 1926 79, and this year 80 per cent., while for the entrants it was 93 per cent. These figures show that the interest and sympathy of the parents are being won. There is need for a full-time dental surgeon and a nurse to help him. The number of children actually treated is still scarcely more than a third of those who were found to need treatment, but a good sign is the fact that the fillings were 105 more than last year. In one small matter we cannot agree with Dr. Corfield. He suggests the possibility that the 50 per cent. fall in cases of defective vision may be due to improved school hygiene; but it is only myopia that is likely to be affected by school conditions, and the myopic children are less than a quarter of the total number suffering from defective vision. However this may be, Colchester may be justly proud of possessing a special class for sight-saving. There is accommodation for 22 children in special schools, and if there was an open-air school the return of exceptional children would be highly creditable.

Glasgow.

The report of Dr. E. T. Roberts is printed as an appendix to that of the Director of Education, and although many interesting facts are included they are set forth chiefly in the form of statistics. The effect of a large immigrant population is seen in the frequent mention of special and industrial schools for Roman Catholics, and it is probably the poor standard of living aggravated by the recent industrial conditions which causes the figures for heights and weights to be considerably below the standard of the anthropometric committee. The educable abnormal children can be dealt with under two great heads: (1) those fit for the special day schools for physically and mentally defectives; (2) those who require change of air with or without special medical attention.

(1) The special day schools and the "annexes" which serve a similar purpose are often arranged for the reception of both mentally and physically defective children—a system not very common in England. The total number of children on attendance in these special schools was 4984. The authority also gives attention to those mentally defective children who have reached 16 years or have been given exemption from school before reaching that age. Three women officers devote their time to keeping in touch with them and, if possible, finding them employment. The accommodation in institutions for those found incapable of receiving benefit from instruction given in special schools is, unfortunately, far too small. The matter is receiving the attention of the authorities concerned.

(2) There is increased accommodation in holiday schools; a new one for girls was set up last year

in the building which was formerly the Hillsfoot Training School of the Delinquency Board, and next year a similar school for boys will be provided. The children in this group are in practice divided into: (a) those requiring an extended period of residence outside the city with special medical attention; and (b) those who require a shorter period under good conditions but without special medical attention. There is now accommodation for both types, the Hillsfoot School receiving 70 Protestant girls of type (b).

The balance of treatment and inspection has been disturbed by the industrial dispute which, by affecting the financial position of many families, caused an increased demand for treatment and consequently a restriction of the time available for medical inspection, so that the number of routine inspections was lower than last year. The number of cases of ear diseases shows a rise of over 20 per cent. The attendances for treatment in general show small increases, but that for ionisation is much higher, indicating the value which is now placed on this treatment. Eye diseases show an increase of 37 per cent., especially in conjunctivitis due to decided epidemics in May and the early summer and in autumn. Affections of the skin in general account for nearly 14,000 cases as against 12,300 last year; impetigo accounts for 1000 of the increase, while scabies has had an increased prevalence for the first time since 1920. Dr. Roberts says that in previous years there has been a tendency for the actual diseases of the skin to decrease and for injuries, abscesses, and burns to increase. This year the accident type of case is six times as common as it was in 1920, but the usual fall in diseases of the skin has been prevented by the industrial conditions. Ringworm, however, has yielded to the influence of the special skin school and X ray treatment to such an extent that the special school has been closed. Necessitous cases of illness, for whom emulsion and drugs were given free, have been nearly 30 per cent. more numerous than last year. Many more teeth were treated this year. In this matter the greater enlightenment of the parents might be held responsible, but it is noteworthy that increase is in extractions and not in fillings.

MENTAL HOSPITAL REPORTS.

THE Derby Borough Mental Hospital had 479 patients on its registers at the end of the year, meaning that there were only 17 vacant beds. The recovery-rate was 22.7 per cent. and the death-rate 6.4 per cent. The cause of death, verified by autopsy in 29 instances, was heart disease in nine patients—the commonest cause. There was no zymotic disease or influenza and only seven patients were under treatment for tuberculosis. The medical superintendent ascribes these satisfactory results to the improved diet and the high standard of nursing. Parole was granted to 40 patients and weekly shopping parties of 30 women go out beyond the estate. A cinema is to be installed and a convalescent hospital and laboratory are needed; at present a small room is set aside for routine pathological investigations. Six nurses obtained their certificate during the year, one with distinction. The committee has also 44 defectives under certificate in various institutions throughout the country. A house is being adapted to form a home for 13 low-grade able-bodied defective girls.

The Wills County Mental Hospital housed 1146 patients at the end of last year, 36 fewer than at the beginning. The recovery-rate was 26.9 per cent. and all but two of those discharged had a probationary period on trial, 18 with money allowances. The death-rate was 9.6 per cent., a large figure almost wholly accounted for by deaths of aged people; the most common causes were tuberculosis, heart disease, and general paralysis. The cause was verified by autopsy in 75.6 per cent. of cases. There was no epidemic, but there were 16 cases of dysentery, six fatal, and two cases of erysipelas. The visiting com-

missioners urge the provision of a laboratory and ultra-violet ray apparatus. A sister tutor has been appointed and ten nurses obtained their certificate during the year. The two out-patient clinics at Swindon and Trowbridge have already justified their existence; 35 patients have attended the former and 31 the latter.

The Roxburgh, Berwick, and Selkirk District Asylum had 363 patients on May 15th, 1928. The recovery-rate for the year was 23.9 per cent., and this low figure and the high death-rate of 13.4 per cent. is ascribed to the large number of aged patients admitted. No less than 42 per cent. of the admissions for the last two years have been senile cases, many almost moribund. Autopsies were held on 25 cases. There was no serious epidemic. Two visiting dental surgeons have attended fortnightly. A cinema has been installed. There are also 57 defectives under the care of the Board. Eleven nurses obtained their certificate during the year, and the number of certificated nurses would be larger but that many leave to obtain a general nursing training—a step which cannot be deplored, although it deprives the institution of valuable service.

MINISTRY OF HEALTH.

ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER.

(Continued from p. 1165.)

TUBERCULOSIS.

THE number of fresh cases of tuberculosis coming to the knowledge of the health authorities during 1927, whether by formal notification under the Tuberculosis Regulations or from other sources, was 77,890. Notification is, on the whole, more effectively carried out year by year, but the reports of medical officers of health show that many deaths from tuberculosis have occurred amongst cases not previously notified. The number of deaths registered from all forms of tuberculosis in England and Wales for 1927 was 38,173. In England, on April 1st, 1928, tuberculosis work was being carried out in 440 dispensaries, and, in addition, 95 other premises were approved for special forms of treatment, including orthopaedic out-patient care of tuberculous cripples after return from residential treatment. There were 378 approved tuberculosis officers. The number of beds allocated to tuberculosis in institutions, excluding 108 institutions concerning which no information is available, is 22,618. The number of patients occupying these beds varies; a certain proportion is always unoccupied particularly in the winter months. On April 1st, 1928, there were 19,710 patients, including 6128 children in the 22,618 beds.

In surveying the question as to how the tuberculosis scheme is working throughout the country, Sir George Newman passes under review problems of notification, diagnosis, bacteriological examinations of sputum, the use of X rays, home visitation, and length of sanatorium treatment. The figures given relating to residential treatment should be studied closely by those anxious to use the available bed accommodation to its utmost. The Ministry suggested in Circular 280 the advisability of differentiating patients into the early, intermediate, and advanced stages. They proposed that early cases or others in which there is hope of definite arrest of disease should be retained for long periods, also advanced cases admitted to institutions because they were dangerously infective; but that the needs of the intermediate class would usually be met by short periods of treatment, repeated when necessary. Yet in some areas a considerable proportion of the intermediate cases were retained in sanatoria for prolonged periods—over six months. The intermittent character of the disease makes it fairly certain that many patients in this class will relapse in any case. It

secondary schools and the continuation school at Rugby. The area is likely to undergo further changes, for by the Act that came into force on April 1st, 2550 school-children were transferred from the authority of the county to that of the extended city of Coventry. The change will mean some adjustment of the nursing staff and two of the clinics for minor ailments will no longer be required. The curtailment of the area may be of advantage, since the present strength of the health visiting staff is only barely sufficient for the ordinary routine work. As a result of an endeavour to economise on the expenditure on operations for tonsils and adenoids, an appeal was made to the medical inspectors to lower their standards and so reduce the number of cases referred for treatment. Accordingly, only 3.9 per cent. of all children have been referred for operation as compared with 6.7 per cent. last year. Such a marked decrease seems scarcely sound; it is not justifiable to allow children to suffer from all the physical and mental handicaps and the economic depreciation caused by obstructions of the nasal passages for a small saving in expenditure. But in many parts of the country there seems to be a tendency to be more conservative in recommending operative treatment, and the decrease may be due to causes other than the desire to economise. Considerable progress has been made in the development of the orthopaedic scheme and most of the county is now covered, but it is held up at Stratford-on-Avon and in the Tamworth district until sufficient funds are forthcoming from the county council. Dr. Hamilton Wood includes in his report a valuable account written by Mr. R. P. Marsh of his work of organising physical education in all its branches. This account appropriately follows the section on orthopaedics, for in this county there is a real unity of all the work designed to promote the right development of the child, from orthopaedic surgery, remedial and physical exercises, to activities like swimming and organised games.

Northumberland.

Arrangements for the care of children in the counties with scattered populations are often less advanced than those in urban districts. Northumberland has still no orthopaedic scheme, efforts to promote one having been frustrated by inability to secure hospital accommodation. One step, however, has been taken in the appointment of an orthopaedic surgeon, Mr. William Mackenzie, and it is hoped that before long some workable plan may be presented. The scheme for the operative treatment of tonsils and adenoids is likely to be considerably extended in the near future. Dr. W. Whitley notes that the incidence of tonsils and adenoids appears to have fallen by 50 per cent. since 1920, and he thinks the fall may be partly due to change of standard; if that be so it is the more important that all those who are recommended for treatment should obtain it. The proposal to appoint a second dentist was not carried out for lack of suitable premises. It is now suggested that a dental van would be of value and would carry treatment into otherwise inaccessible places. Reports from other counties similarly placed, such as Cumberland where this device has been tried, show that it has proved very useful. The dental surgeon, Miss C. M. Anderson, deplors the prevalence of dental caries in infants; there is a general lack of oral hygiene and the children are neither trained nor interested in care of the mouth and teeth. That ignorance rather than apathy is the obstacle is shown by the fact that children who have been previously treated and inspected usually maintain better oral hygiene than the rest. Miss M. Wardle, organiser of physical training, writes of the importance of good posture and its important bearing on good health and hygiene. There are no special schools belonging to the local authority in Northumberland, and many defective children of all kinds still attend elementary schools or receive no education of any kind.

Colchester.

The report of Dr. W. F. Corfield shows that steady progress is being made. The actual number of routine inspections has fallen by 200; this is partly due to the decrease in the number of children reaching the age for medical inspection (which is more or less general over the country), and partly to an accidental local factor, the reduction in the number of children in two schools owing to an outbreak of measles and also to the illness of a school nurse. Of the orthopaedic clinic Dr. Corfield says that the good work done has been far greater than he expected, and that every year a larger number of children who would have grown up with a deformity such as a club-foot are now discovered in time, and if they are not completely cured the deformity is so modified and moulded that a limb which would have been unsightly and almost useless is made strong and useful. The orthopaedic surgeon, Mr. Whitchurch Howell, sees also infants referred from the infant welfare department, and it is hoped that next year he will have the assistance of a nurse trained to give remedial exercises. A testimonial to the work done in Colchester is the large and increasing percentage of parents attending medical inspections; in 1925 it was 77, in 1926 79, and this year 80 per cent., while for the entrants it was 93 per cent. These figures show that the interest and sympathy of the parents are being won. There is need for a full-time dental surgeon and a nurse to help him. The number of children actually treated is still scarcely more than a third of those who were found to need treatment, but a good sign is the fact that the fillings were 105 more than last year. In one small matter we cannot agree with Dr. Corfield. He suggests the possibility that the 50 per cent. fall in cases of defective vision may be due to improved school hygiene; but it is only myopia that is likely to be affected by school conditions, and the myopic children are less than a quarter of the total number suffering from defective vision. However this may be, Colchester may be justly proud of possessing a special class for sight-saving. There is accommodation for 22 children in special schools, and if there was an open-air school the return of exceptional children would be highly creditable.

Glasgow.

The report of Dr. E. T. Roberts is printed as an appendix to that of the Director of Education, and although many interesting facts are included they are set forth chiefly in the form of statistics. The effect of a large immigrant population is seen in the frequent mention of special and industrial schools for Roman Catholics, and it is probably the poor standard of living aggravated by the recent industrial conditions which causes the figures for heights and weights to be considerably below the standard of the anthropometric committee. The educable abnormal children can be dealt with under two great heads: (1) those fit for the special day schools for physically and mentally defectives; (2) those who require change of air with or without special medical attention.

(1) The special day schools and the "annexes" which serve a similar purpose are often arranged for the reception of both mentally and physically defective children—a system not very common in England. The total number of children on attendance in these special schools was 4981. The authority also gives attention to those mentally defective children who have reached 16 years or have been given exemption from school before reaching that age. Three women officers devote their time to keeping in touch with them and, if possible, finding them employment. The accommodation in institutions for those found incapable of receiving benefit from instruction given in special schools is, unfortunately, far too small. The matter is receiving the attention of the authorities concerned.

(2) There is increased accommodation in holiday schools; a new one for girls was set up last year.

in the building which was formerly the Hillsfoot Training School of the Delinquency Board, and next year a similar school for boys will be provided. The children in this group are in practice divided into: (a) those requiring an extended period of residence outside the city with special medical attention; and (b) those who require a shorter period under good conditions but without special medical attention. There is now accommodation for both types, the Hillsfoot School receiving 70 Protestant girls of type (b).

The balance of treatment and inspection has been disturbed by the industrial dispute which, by affecting the financial position of many families, caused an increased demand for treatment and consequently a restriction of the time available for medical inspection, so that the number of routine inspections was lower than last year. The number of cases of ear diseases shows a rise of over 20 per cent. The attendances for treatment in general show small increases, but that for ionisation is much higher, indicating the value which is now placed on this treatment. Eye diseases show an increase of 37 per cent., especially in conjunctivitis due to decided epidemics in May and the early summer and in autumn. Affections of the skin in general account for nearly 14,000 cases as against 12,300 last year; impetigo accounts for 1000 of the increase, while scabies has had an increased prevalence for the first time since 1920. Dr. Roberts says that in previous years there has been a tendency for the actual diseases of the skin to decrease and for injuries, abscesses, and burns to increase. This year the accident type of case is six times as common as it was in 1920, but the usual fall in diseases of the skin has been prevented by the industrial conditions. Ringworm, however, has yielded to the influence of the special skin school and X ray treatment to such an extent that the special school has been closed. Necessitous cases of illness, for whom emulsion and drugs were given free, have been nearly 30 per cent. more numerous than last year. Many more teeth were treated this year. In this matter the greater enlightenment of the parents might be held responsible, but it is noteworthy that increase is in extractions and not in fillings.

MENTAL HOSPITAL REPORTS.

THE *Derby Borough Mental Hospital* had 479 patients on its registers at the end of the year, meaning that there were only 17 vacant beds. The recovery-rate was 22.7 per cent. and the death-rate 6.4 per cent. The cause of death, verified by autopsy in 29 instances, was heart disease in nine patients—the commonest cause. There was no zymotic disease or influenza and only seven patients were under treatment for tuberculosis. The medical superintendent ascribes these satisfactory results to the improved diet and the high standard of nursing. Parole was granted to 40 patients and weekly shopping parties of 20 women go out beyond the estate. A cinema is to be installed and a convalescent hospital and laboratory are needed; at present a small room is set aside for routine pathological investigations. Six nurses obtained their certificate during the year, one with distinction. The committee has also 44 defectives under certificate in various institutions throughout the country. A house is being adapted to form a home for 13 low-grade able-bodied defective girls.

The *Wills County Mental Hospital* housed 1146 patients at the end of last year, 30 fewer than at the beginning. The recovery-rate was 26.9 per cent. and all but two of those discharged had a probationary period on trial, 18 with money allowances. The death-rate was 9.6 per cent., a large figure almost wholly accounted for by deaths of aged people; the next commonest causes were tuberculosis, heart disease, and general paralysis. The cause was verified by autopsy in 75.6 per cent. of cases. There was no epidemic, but there were 16 cases of dysentery, six fatal, and two cases of erysipelas. The visiting com-

missioners urge the provision of a laboratory and ultra-violet ray apparatus. A sister tutor has been appointed and ten nurses obtained their certificate during the year. The two out-patient clinics at Swindon and Trowbridge have already justified their existence; 35 patients have attended the former and 31 the latter.

The *Roxburgh, Berwick, and Selkirk District Asylum* had 363 patients on May 15th, 1928. The recovery-rate for the year was 23.9 per cent., and this low figure and the high death-rate of 13.4 per cent. is ascribed to the large number of aged patients admitted. No less than 42 per cent. of the admissions for the last two years have been senile cases, many almost moribund. Autopsies were held on 25 cases. There was no serious epidemic. Two visiting dental surgeons have attended fortnightly. A cinema has been installed. There are also 57 defectives under the care of the Board. Eleven nurses obtained their certificate during the year, and the number of certificated nurses would be larger but that many leave to obtain a general nursing training—a step which cannot be deplored, although it deprives the institution of valuable service.

MINISTRY OF HEALTH.

ANNUAL REPORT OF THE CHIEF MEDICAL OFFICER.

(Concluded from p. 1165.)

TUBERCULOSIS.

THE number of fresh cases of tuberculosis coming to the knowledge of the health authorities during 1927, whether by formal notification under the Tuberculosis Regulations or from other sources, was 77,890. Notification is, on the whole, more effectively carried out year by year, but the reports of medical officers of health show that many deaths from tuberculosis have occurred amongst cases not previously notified. The number of deaths registered from all forms of tuberculosis in England and Wales for 1927 was 38,173. In England, on April 1st, 1928, tuberculosis work was being carried out in 440 dispensaries, and, in addition, 95 other premises were approved for special forms of treatment, including orthopaedic out-patient care of tuberculous cripples after return from residential treatment. There were 378 approved tuberculosis officers. The number of beds allocated to tuberculosis in institutions, excluding 108 institutions concerning which no information is available, is 22,618. The number of patients occupying these beds varies: a certain proportion is always unoccupied particularly in the winter months. On April 1st, 1928, there were 19,710 patients, including 6128 children in the 22,618 beds.

In surveying the question as to how the tuberculosis scheme is working throughout the country, Sir George Newman passes under review problems of notification, diagnosis, bacteriological examinations of sputum, the use of X rays, home visitation, and length of sanatorium treatment. The figures given relating to residential treatment should be studied closely by those anxious to use the available bed accommodation to its utmost. The Ministry suggested in Circular 280 the advisability of differentiating patients into the early, intermediate, and advanced stages. They proposed that early cases or others in which there is hope of definite arrest of disease should be retained for long periods, also advanced cases admitted to institutions because they were dangerously infective; but that the needs of the intermediate class would usually be met by short periods of treatment, repeated when necessary. Yet in some areas a considerable proportion of the intermediate cases were retained in sanatoria for prolonged periods—over six months. The intermittent character of the disease makes it fairly certain that many patients in this class will relapse in any case. It

secondary schools and the continuation school at Rugby. The area is likely to undergo further changes, for by the Act that came into force on April 1st, 2550 school-children were transferred from the authority of the county to that of the extended city of Coventry. The change will mean some adjustment of the nursing staff and two of the clinics for minor ailments will no longer be required. The curtailment of the area may be of advantage, since the present strength of the health visiting staff is only barely sufficient for the ordinary routine work. As a result of an endeavour to economise on the expenditure on operations for tonsils and adenoids, an appeal was made to the medical inspectors to lower their standards and so reduce the number of cases referred for treatment. Accordingly, only 3.9 per cent. of all children have been referred for operation as compared with 6.7 per cent. last year. Such a marked decrease seems scarcely sound; it is not justifiable to allow children to suffer from all the physical and mental handicaps and the economic depreciation caused by obstructions of the nasal passages for a small saving in expenditure. But in many parts of the country there seems to be a tendency to be more conservative in recommending operative treatment, and the decrease may be due to causes other than the desire to economise. Considerable progress has been made in the development of the orthopaedic scheme and most of the county is now covered, but it is held up at Stratford-on-Avon and in the Tamworth district until sufficient funds are forthcoming from the county council. Dr. Hamilton Wood includes in his report a valuable account written by Mr. R. P. Marsh of his work of organising physical education in all its branches. This account appropriately follows the section on orthopaedics, for in this county there is a real unity of all the work designed to promote the right development of the child, from orthopaedic surgery, remedial and physical exercises, to activities like swimming and organised games.

Northumberland.

Arrangements for the care of children in the counties with scattered populations are often less advanced than those in urban districts. Northumberland has still no orthopaedic scheme, efforts to promote one having been frustrated by inability to secure hospital accommodation. One step, however, has been taken in the appointment of an orthopaedic surgeon, Mr. William Mackenzie, and it is hoped that before long some workable plan may be presented. The scheme for the operative treatment of tonsils and adenoids is likely to be considerably extended in the near future. Dr. W. Whitley notes that the incidence of tonsils and adenoids appears to have fallen by 50 per cent. since 1920, and he thinks the fall may be partly due to change of standard; if that be so it is the more important that all those who are recommended for treatment should obtain it. The proposal to appoint a second dentist was not carried out for lack of suitable premises. It is now suggested that a dental van would be of value and would carry treatment into otherwise inaccessible places. Reports from other counties similarly placed, such as Cumberland where this device has been tried, show that it has proved very useful. The dental surgeon, Miss C. M. Anderson, deplores the prevalence of dental caries in infants; there is a general lack of oral hygiene and the children are neither trained nor interested in care of the mouth and teeth. That ignorance rather than apathy is the obstacle is shown by the fact that children who have been previously treated and inspected usually maintain better oral hygiene than the rest. Miss M. Wardle, organiser of physical training, writes of the importance of good posture and its important bearing on good health and hygiene. There are no special schools belonging to the local authority in Northumberland, and many defective children of all kinds still attend elementary schools or receive no education of any kind.

Colchester.

The report of Dr. W. F. Corfield shows that steady progress is being made. The actual number of routine inspections has fallen by 200; this is partly due to the decrease in the number of children reaching the age for medical inspection (which is more or less general over the country), and partly to an accidental local factor, the reduction in the number of children in two schools owing to an outbreak of measles and also to the illness of a school nurse. Of the orthopaedic clinic Dr. Corfield says that the good work done has been far greater than he expected, and that every year a larger number of children who would have grown up with a deformity such as a club-foot are now discovered in time, and if they are not completely cured the deformity is so modified and moulded that a limb which would have been unsightly and almost useless is made strong and useful. The orthopaedic surgeon, Mr. Whitchurch Howell, sees also infants referred from the infant welfare department, and it is hoped that next year he will have the assistance of a nurse trained to give remedial exercises. A testimonial to the work done in Colchester is the large and increasing percentage of parents attending medical inspections; in 1925 it was 77, in 1926 79, and this year 80 per cent., while for the entrants it was 93 per cent. These figures show that the interest and sympathy of the parents are being won. There is need for a full-time dental surgeon and a nurse to help him. The number of children actually treated is still scarcely more than a third of those who were found to need treatment, but a good sign is the fact that the fillings were 105 more than last year. In one small matter we cannot agree with Dr. Corfield. He suggests the possibility that the 50 per cent. fall in cases of defective vision may be due to improved school hygiene; but it is only myopia that is likely to be affected by school conditions, and the myopic children are less than a quarter of the total number suffering from defective vision. However this may be, Colchester may be justly proud of possessing a special class for sight-saving. There is accommodation for 22 children in special schools, and if there was an open-air school the return of exceptional children would be highly creditable.

Glasgow.

The report of Dr. E. T. Roberts is printed as an appendix to that of the Director of Education, and although many interesting facts are included they are set forth chiefly in the form of statistics. The effect of a large immigrant population is seen in the frequent mention of special and industrial schools for Roman Catholics, and it is probably the poor standard of living aggravated by the recent industrial conditions which causes the figures for heights and weights to be considerably below the standard of the anthropometric committee. The educable abnormal children can be dealt with under two great heads: (1) those fit for the special day schools for physically and mentally defectives; (2) those who require change of air with or without special medical attention.

(1) The special day schools and the "annexes" which serve a similar purpose are often arranged for the reception of both mentally and physically defective children—a system not very common in England. The total number of children on attendance in these special schools was 4984. The authority also gives attention to those mentally defective children who have reached 16 years or have been given exemption from school before reaching that age. Three women officers devote their time to keeping in touch with them and, if possible, finding them employment. The accommodation in institutions for those found incapable of receiving benefit from instruction given in special schools is, unfortunately, far too small. The matter is receiving the attention of the authorities concerned.

(2) There is increased accommodation in holiday schools; a new one for girls was set up last year.

sidered by the tuberculin committee of the Council, who have advised that no useful purpose would be served by meeting these requests.

A useful recapitulation of our present knowledge of immunisation by Prof. Calmette's method of prophylactic vaccination of the new-born is included.

Prof. Major Greenwood, F.R.S., on behalf of the Medical Research Council Committee, has examined Dr. Biraud's report on 1537 infants brought up in a tuberculous environment, who had been vaccinated during the years 1924 to 1926. Of these 1050 had been in contact with tuberculous people and 487 in contact with tuberculous mothers. The general mortality from all causes in the two groups during the first year of life was 7.6 per cent. and 6.6 per cent., while the mortality from tuberculosis during the first year of life was 1.55 per cent. and 2.46 per cent. According to Calmette, a comparison of the mortality of vaccinated and unvaccinated children in contact with tuberculous mothers brought out striking results: the rate for the former was 6.6 per cent., and that for the latter 24 per cent. Prof. Greenwood considers that the mortality in the first year of life of the vaccinated children is no worse than that of ordinary children. Hence, if it could be shown that the rate of mortality of children of the class living in tuberculous homes is very much worse than the average, a *prima facie* case in favour of the process would have been made out.

It is clear that much more detailed information is necessary, especially of the mortality rates of vaccinated children brought up in contact with tuberculous mothers, before Calmette's claims can be completely accepted.

The provision of X ray facilities for purposes of diagnosis and to check the progress of a pneumothorax is commended. With the present facilities for the artificial light treatment of lupus there should be no need, in Sir George Newman's view, for utilising X rays in the treatment of this disease; the last-named practice involves serious risk of the appearance of carcinoma in the treated area.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 8TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 155 (last week 189); scarlet fever, 2864; diphtheria, 1360; enteric fever, 39; pneumonia, 1133; puerperal fever, 46; puerperal pyrexia, 117; cerebro-spinal fever, 12; acute poliomyelitis, 9; encephalitis lethargica, 19; dysentery, 18; ophthalmia neonatorum, 97. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board¹ on Dec. 11th-12th was as follows:—Small-pox, under treatment 14; scarlet fever, 2488; diphtheria, 2129; enteric fever, 16; measles, 53; whooping-cough, 390; puerperal fever, 18 (plus 7 babies); encephalitis lethargica, 74; poliomyelitis, 4; "other diseases," 14. At St. Margaret's Hospital there were 6 babies (plus 2 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 18 (6) from measles, 8 (2) from scarlet fever, 30 (6) from whooping-cough, 30 (8) from diphtheria, 51 (7) from diarrhoea and enteritis under two years, and 60 (10) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Bristol and Manchester. Liverpool reported 3 deaths from measles, and Manchester 3 from whooping-cough. The largest number of fatal cases of diphtheria were reported from Birmingham 8, Manchester 6, Liverpool and Salford 4 each (Glasgow 5, Belfast 8). No town reported more than 2 deaths from influenza except Birmingham 5, Leicester and Rochdale 3 each (Glasgow 7).

The number of stillbirths registered during the week in the great towns was 287 (corresponding to a rate of 11 per thousand births, including 51 in London).

¹ It is noted that seven cases of cancer of the uterus were reported from North-Western Hospital.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Report of the Registrar-General of the Irish Free State.

THE Registrar-General's report for 1927 shows that the number of deaths registered in that year was greater than in the previous, whilst marriages and births were less. The excess of births over deaths was more than balanced by the net emigration. The death-rate was 14.77 per 1000 of the estimated population, which is lower than the average rate for the previous ten years (15.39), but higher than the rate for 1926 (14.05). The increase in the number of deaths was chiefly due to influenza, heart diseases, and respiratory diseases. The principal epidemic diseases continued to decrease. The number of deaths from tuberculosis was the lowest recorded, the rate being 1.45 per 1000 of the population. The corresponding rate in Northern Ireland was 1.41, in England and Wales 0.97, and in Scotland 1.0. The deaths from cancer continued to increase, the total number, 3113, being the highest recorded. The increase of 92 over 1926 occurred entirely among males. The increase in cancer has not been continued from year to year, but successive rises suggest that the disease is advancing. Heart diseases were responsible for 5031 deaths, almost equally distributed between the sexes—2439 of males and 2592 of females. The number of deaths under this heading was 375 above that for 1926 and 275 above the average for the ten years 1917-26. The death of infants under one year of age showed a mortality-rate over the whole country of 71 per 1000 births, as compared with 74 per 1000 in 1926. In Northern Ireland the rate was 78, in England and Wales 70, and in Scotland 89. The low rate in the Irish Free State is due to the very low mortality (56 per 1000) in rural areas. In urban areas the rate was 99, and in the city of Dublin 123. The rate among illegitimate children is, however, startlingly high—288 per 1000—or more than four times the mortality among legitimate children.

The births registered during the year represented a rate of 20.31 per 1000 of the population, being 0.05 below the average for the previous ten years. The birth-rate in Northern Ireland was 21.3, in England and Wales 16.6, and in Scotland 19.8. Marriages gave a rate of 4.54 per 1000 of the population, a rate 0.03 below that for 1926 and 0.44 below the average for the ten years 1917-26. The number of emigrants in 1927 was 27,309, and the number of immigrants 2084, resulting in a net loss of 25,225. Of the 27,309 who left the country 23,947 went to the United States of America.

Celebrations at Trinity College, Dublin.

Dublin University was engaged last week in celebrating the bicentenary of the birth of two of her greatest sons—Oliver Goldsmith and Edmund Burke. Mr. Stephen Gwynn delivered an oration on Goldsmith and Lord Birkenhead one on Burke. Mr. Gwynn's address concerned itself mainly with the personal life of his subject, with a brief estimation of his position in literature. He did not pay special attention to the medical side of Goldsmith's career. The most interesting part of the celebration—and perhaps that which honoured most the spirit of both Burke and Goldsmith—was an admirable inter-university debate in which young men from the Universities of Oxford, Cambridge, Edinburgh, and Paris, and from University College, Dublin, took part with young men of Trinity College, Dublin. The subject was: That a Censorship of Literature is Desirable. The motion was defeated by a large majority.

DONCASTER INFIRMARY.—By weekly deductions of twopence from their wages miners in the Doncaster district this year have contributed £600 to Doncaster Infirmary. In six years the total has reached £12,000.

appears to be a sounder policy to give an intermediate case the shortest period of treatment which will restore his working capacity, and to readmit him for further short periods when relapses occur or appear to be imminent. On the other hand, the figures in column 36 are disappointing in the other direction, as indicating that many cases, presumably of the class in which complete arrest is possible, have been retained in residential institutions for quite inadequate periods. For the country as a whole only 22.5 per cent. of these cases stayed over six months. Local authorities and the general public should clearly understand that tuberculosis cannot be arrested by the sanatorium method unless that method is given a proper chance. Unfortunately, the period of stay is not the only factor which has mitigated against recovery. Sir George Newman concludes that—

(1) The principle of the sanatorium method is sound, and there is at present no alternative principle available.

(2) The sanatorium system, that is to say, the method or organisation by which the principle is practised, may be, and often is, faulty. It is always in need of vigilant supervision if it is to deliver the results desired.

(3) The critical issue must always be the effective intensive treatment of each patient, on his merits or demerits of physiology, pathology, and psychology. There can be no adoption of a "rule of thumb" practice.

He adds it is difficult to escape the conclusion that the superintendent is not always giving sufficient attention to the method and organisation of his sanatorium or sufficient intensive study to each individual case in his charge.

The Results of Sanatorium Treatment.

Unless a satisfactory proportion of the pulmonary cases classed as early can be classified as "quiescent" on discharge from residential treatment, the questions may well be asked:—

(a) Is such failure due to the type of the institution and the character of the treatment given thereat?

(b) Is it due to the fact that the duration of the patient's stay has been too short?

(c) In the case of the Class T.B. minus, is it due to the fact that intermediate and advanced cases have been wrongly included (through failure to have the sputum examined) in a group which should consist of early cases?

On the answer to these questions and the action taken thereon will depend very largely the future success of any sanatorium scheme, and the retention of public confidence in the value of sanatorium treatment. A few weeks ago a public statement was made by a representative medical man in regard to sanatorium treatment in England. He is reported to have said:—

"However useful sanatoria may be from a preventive point of view or as a means of segregating tubercular people, they are from a curative point of view I am afraid of little, if any, use. . . . In fact, the sanatorium method can only show 14 per cent. of cures, which is very low, whereas other methods can show 70 per cent. and 80 per cent. of cures."

This declaration was founded, according to information received, on the results obtained at one particular sanatorium in this country and upon an alternative method of treatment. If the statement be accurate, it is obvious that the State should direct its available resources not towards sanatorium treatment but towards some alternative method.

It is far from an easy matter to assess precisely the value of sanatorium treatment as indicated by the percentage of "cures" obtained. Certain other methods of estimating its value, however, are available. Substantial data exist for our general guidance, and these may be illustrated in three groups of facts.

In the first place, we may take into consideration the broad fact that from 1913 to 1926 there were in England and Wales 1,191,910 persons notified as suffering from tuberculosis (including those certified as having died between 1913 and 1926 inclusive). During that same period, 1913-

1926, the total number of deaths certified as due to this disease was 656,049. This leaves 535,861 tuberculosis patients as not having died from tuberculosis within that period, which gives us a survival rate of approximately 50 per cent., even though many of the known cases which died never received treatment under any public scheme.

Obviously this does no more than present a general picture of "recoverability," with or without sanatorium treatment or any treatment. From 1817 to 1926 the mortality from tuberculosis of the respiratory system in this country declined from 3189 per million to 730 per million, an astounding fall, and, moreover, recovery from small degrees of tuberculous infection is a matter of daily experience. In fact, under favourable conditions and in its early stages tuberculosis shows probably a higher degree of recoverability than any other of the great constitutional diseases. In the second place, while it is true that some sanatoria, indifferently conducted or unfavourably placed as regards the severity of the cases admitted, yield a small proportion of recoveries—i.e., cases classified on discharge as "quiescent"—it is equally true that a properly organised sanatorium system shows good results. For example, in Lancashire in 1926 over 80 per cent. of early cases were quiescent or improved on discharge.

After-care.

The importance of "after-care" in enabling patients to obtain the full advantage of treatment in residential institutions and in helping them subsequently to obtain suitable conditions of living and occupation is emphasised. Unfortunately there are many areas where no arrangements for care work have yet been made. One of the greatest difficulties in connexion with this work is that in some areas care committee workers do not realise how much efficient work can be done by advice and personal assistance in individual cases at trivial cost, and think that no useful work can be carried out unless ample funds are at their disposal. It is not suggested that many care committees do not require funds to enable them to carry out their work to the greatest advantage; but it is certain that much useful work can be carried out in the absence of such funds. The patient may need advice with respect to pensions, sickness benefit, assistance in obtaining a more suitable house or employment, the loan of a bed or help in providing for his family during treatment in a sanatorium. Frequently organisations exist which can afford the needful help, and the function of the care committee in these cases is to bring the patient into touch with the appropriate organisation.

Workshops and other schemes, such as the village settlements at Papworth and Preston Hall for the employment of tuberculous workers, are praised by Sir George Newman.

Methods of Treatment.

Of artificial pneumothorax in suitable cases he speaks highly, but is less confident as to the benefit obtained from other operative procedures, such as phrenic crulsion and thoracoplasty. Such methods are anyhow reserved for particularly selected hospital cases, and should be undertaken only by competent and experienced surgeons.

As to the treatment by gold salts, the recent clinical evidence concerning *sanoerysin* is reviewed at some length. It seems clear, he says, that *sanoerysin* is a form of treatment that is of limited application, and can only be given to carefully selected cases under constant medical supervision, and with due appreciation of its risks and contra-indications. Further experimental work on the effects of *sanoerysin* is being done by Prof. S. L. Cummins at Cardiff, under the auspices of the Medical Research Council.

From time to time the Ministry and the Medical Research Council receive representations from outside which urge the need for new investigations of the clinical value of *tuberculin* in the treatment of human tuberculosis. This question has recently been con-

neutrophilia of suddenly intercurrent sepsis, even where a total leucopenia exists from other causes. These, he says, may be easily missed if it is not the percentage count that is before the physician, although in purely scientific investigations absolute counts must be obtained.—I am, Sir, yours faithfully,
Kew, Dec. 15th, 1928. W. E. HOME.

THE RODS AND CONES.

To the Editor of THE LANCET.

SIR,—Mr. Edridge-Green's letter in your issue of Dec. 15th is anything but convincing. The absence of discussion on a paper at an international meeting may have other reasons than approval, upon which I need not enlarge. In his book on Colour-blindness in the International Scientific Series, Mr. Edridge-Green describes an experiment in support of his theory. It is shortly this: If we view a luminous object through an artificial pupil, a pinhole in a piece of paper, it has a certain brightness. If we move the artificial pupil away from the eye towards the object, the object becomes brighter. The reason is, says Mr. Edridge-Green, by moving the paper away from the eye, more light falls on the translucent sclerotic, more visual purple is liberated, and hence the object appears brighter. This would be in harmony with his theory, but unhappily he has misread the facts. There is a very simple elementary physical explanation for this observation. In moving the pinhole away from the eye towards the luminous object, it is moved towards the apex of the conical pencils of light from all the points of the luminous object—i.e., more light-energy from every point passes through the pinhole, and hence the object appears brighter. Now for a crucial experiment of Mr. Edridge-Green's explanation. I placed an electric bulb, with no current passing, next to my eye, viewed a luminous object through a pinhole and noted its brightness. Then I switched on the lamp. A great amount of light fell on the sclerotic and should have, according to Mr. Edridge-Green's theory, liberated more visual purple and increased the brightness of the object looked at, but the brightness of the object remained unaltered. I described, possibly demonstrated, the experiment to Mr. Edridge-Green, some 15 years or so ago at the Psychological Laboratory at University College. He thought it very interesting, but having no time to discuss it then, promised to return and discuss it later. However, this never happened.

A point in favour of v. Kries's theory, and easily observable by everyone, is this: If, when noticing a star of the lesser magnitudes in the peripheral field, we look at it directly (i.e., the star's image then falls on the fovea), it disappears, but as soon as we look at a point nearly by the star at once appears again in the peripheral field.—I am, Sir, yours faithfully,
Shortlands, Dec. 15th, 1928. A. WOHLGEMUTH.

SACRO-ILIAC PAIN OR SCIATICA?

To the Editor of THE LANCET.

SIR,—On more than one occasion you have allowed me to draw attention in your columns to various aspects of sacro-iliac pain, believing, as I do, that an immense amount of human suffering will be alleviated when pain from this source becomes generally recognised amongst the members of our profession. Then the treatment of pain in the lower part of the back may be placed on a more scientific basis than at the present time. It was therefore with the greatest pleasure that I read the address on sacro-iliac pain by Dr. Wilfred Harris on p. 1230 of your last issue. In this address Dr. Harris states that

"The pain sign in sciatica is the production of pain referred along the nerve when the leg is extended on the sacro-iliac articulation."

And then adds that we should—

"limit the value of his sign of sacro-iliac sprain to those cases in which the pain is referred to the actual joint region, whether or no there is also pain referred down the leg."

For many years past I have used this test with a very slight and simple addition which is, I think, conclusive in the differential diagnosis between the two complaints. When the hip is flexed and the knee is extended, the ankle-joint, being in a position of rest, is definitely plantar-flexed. When the movement has reached a stage at which pain is first felt, dorsi-flexion of the foot will lay no extra tension on the ham strings, and therefore on the sacro-iliac joint; while this movement must of necessity increase the tension on the terminal branches of the sciatic nerve. If, therefore, dorsi-flexion of the foot increases the pain in this position, it is safe to make a definite diagnosis of sciatica. If it fails to do so, the chances are very largely that the cause of the pain is due to a lesion of the sacro-iliac joint. Of course, it cannot be too strongly emphasised that the differential diagnosis of pain arising in the lower part of the back is so difficult and so complicated that it is impossible to rely on any one sign, but the sign I am now suggesting has withstood the test in the examination of many hundreds of cases, and it is but rarely that doubt has been thrown on its accuracy by the rest of the examination.

I do not know whether this observation has been published before. If so I am unaware of it, although many know of it, as I have frequently drawn attention to the value of the sign when lecturing on back-ache and allied troubles during the last seven years.

I am, Sir, yours faithfully,

JAMES MENNELL, M.D. Camb.

Park-crescent, W., Dec. 17th 1928.

CHILLY FEET.

To the Editor of THE LANCET.

SIR,—Repeated chilling of the feet is, no doubt, like other sorts of chilling, a common cause of illnesses of various kinds. Pasteur long ago found out that in poultry it brought on chicken cholera. That is to say, it lowered the resistance of the body so as to convert immunity into liability. I believe that a large proportion of the chills contracted in the winter months commence in the feet and are attributable to unsuitable footwear. We know that unless the leather is of good quality, and properly sewn and waterproofed, a boot or shoe must admit moisture. Feet shod in damp leather suffer from a double adverse exchange. They receive moisture from the ground, and lose heat to the ground. In the warm air of the house the loss of heat by evaporation also chills the feet. Everyone removes damp gloves on coming indoors. If persons with poor circulation always removed their outdoor shoes, like the French peasants, when they come into the house, they would find it easier to keep warm.

The wearer of sabots is in a happier case, for wood is a non-conductor, and sabots or light, well-made clogs, such as are used in gardening, keep the feet surprisingly warm and comfortable. So long as the feet are kept warm moisture is not injurious. Rubber over-shoes or the modern rubber boots over thick stockings keep the feet both dry and warm in winter since rubber also is a non-conductor. The drawback of rubber soles is that moisture is apt to creep in and be retained between the sole and the leather. Half-Wellingtons and high spats are, as is well known, useful for chilly feet in another way. If the ankles are not kept warm the blood-vessels contract and the blood-supply to the feet is diminished. Sats warm the feet and mittens warm the fingers by maintaining the blood-supply.

My reference, in a recent lecture at the Royal Institute of Public Health, to the methods of Kneipp at Worshofen has caused some surprise. It does seem

CHRONIC SPASMODIC AFFECTIONS OF THE COLON.

To the Editor of THE LANCET.

SIR,—Dr. Ryle kindly refers to my book upon "Tonic Hardening of the Colon." I feel certain, however, that further study of this subject will show that the term "spasmodic" as applied to the condition referred to is not a satisfactory one even in the case of the small "contracted" colon which is sometimes shown by radiographs. Although spasm of the colon probably does occur it will, I feel sure, be ultimately agreed that the commonest cause of colon hardening is not muscular contraction but a tonic static fixation of some of the muscular fibres, a form of primitive muscular activity allied to the "postural activity" first described by Sir Charles Sherrington. It is, therefore, preferable to describe this condition as simply "tonic hardening" instead of using a term which implies a theory as to the cause of the hardening which further observation may prove to be incorrect.

I feel I must also offer a criticism of Dr. Cawadias's statement that "a precise knowledge of visceral neurology" is necessary for the accurate diagnosis of this condition. For more than 35 years I have noted the degree of hardening of the colon in nearly every patient that I have examined, and I have found that very simple measures suffice to control this so-called "spasmodic" condition when it occurs. As a rule this abnormal hardness of the colon speedily subsides if the patient be given an effective intestinal antiseptic combined with full doses of some drug containing atropine, preferably tincture of hyoscyamus in 20 to 30 minims doses.

In connexion with Dr. Crookshank's remarks as to the efficacy of psychotherapy, I feel sure that if he took two parallel series of cases showing abnormal hardness ("spasm") of the colon and treated the one series by psychotherapy and the other by means of full doses of hyoscyamus, together with salol in 10 gr. doses thrice daily (or, where not contraindicated, the mercury and iron antiseptic) and with proper regulation of the diet, he would find that the latter series would show far better results than the former.

Finally, with regard to Dr. Ryle's criticism that in my book I have overstressed the effect of colon hardening in causing nervous symptoms, I would like to point out that cases of this nature showing mental depression, obsessions, &c., often have no abdominal symptoms whatever, and the colon might be thought to be perfectly normal were it not for the fact that on palpation it was found to be hard and tender. The rapidity with which such cases yield to treatment by an intestinal antiseptic, hyoscyamus, and diet is often quite dramatic.

I am, Sir, yours faithfully,
Birmingham, Dec. 15th, 1928. T. STACEY WILSON.

PURE NEPHROSIS.

To the Editor of THE LANCET.

SIR.—In your account (p. 1240) of the discussion on "Purines as Diuretics" at the Royal Society of Medicine it is stated that I described pure nephrosis "as a functional imitation of what happened in mercuric chloride poisoning." Though I am myself doubtless responsible for this statement, I should be much obliged if you would give me an opportunity of shortly explaining my views on a subject which has greatly interested me. I have formerly had the opportunity of observing rapid recovery in cases of apparently pure nephrosis after many months of "waterlogged" condition, and in one similar case

have unfortunately seen death occur following convulsions which supervened just when an intercurrent infection had been apparently recovered from. Such convulsions would have been formerly termed acute uræmic convulsions, though they are now known not to be really uræmic. They are probably due to spreading of the general oedematous process and the onset of intracranial oedema.

What I should have said in my remarks is that pure nephrosis is a disturbance in renal function of the same nature as that which occurs during one stage or degree of mercuric chloride poisoning. The condition of pure nephrosis is possible, I believe, in only very few individuals, and is best explained, according to my views, as the result of an idiosyncratic response on the part of the epithelium of the convoluted tubules towards certain microbial toxins (in some cases, for instance, the toxin of syphilis, just before the outbreak of ordinary secondary syphilitic manifestations). Non-microbial poisons, such as chloroform, may produce similar "parenchymatous" disturbance both in the kidney and liver at the same time.

In microscopic sections of the kidney from rare fatal cases of pure nephrosis (formerly classed as pure parenchymatous nephritis) the glomeruli appear not to be diseased, but the cells of the convoluted tubules are swollen and desquamating and appear to be blocking the dilated tubules. This is the "large white kidney" of pure nephrosis, which is to be distinguished from the "large white kidney" of amyloid disease and from the kidney of "lipoid nephrosis." The cortex of the latter is speckled with lipid deposits (cholesterol), and also nearly always presents obvious signs of an old interstitial inflammatory process.

In pure nephrosis, according to the view that I am explaining, the swelling of the epithelium of the convoluted tubules is sufficient to partially (very rarely completely) obstruct the outflow of water and sodium chloride from the glomeruli and thus gives rise to the great diminution of urine, the retention of water and sodium chloride, and the general dropsy (waterloggedness) of the clinical picture; whereas just sufficient water probably passes through most of the convoluted tubules to carry away the urea excreted by the glandular cells of the tubules and thus prevent its undue accumulation in the blood.

In such matters mechanical explanations are not to be lightly accepted, but it seems to me that one is driven to some such theory as the above, which is after all very similar, I believe, to that most generally held at present.

I am, Sir, yours faithfully,
London, W., Dec. 16th, 1928. F. PARKES WEBER.

THE MODE OF EXPRESSING THE DIFFERENTIAL LEUCOCYTE COUNT.

To the Editor of THE LANCET.

SIR,—As the question of absolute or percentage leucocyte counts has been raised, I would say that Prof. Schilling has discussed this matter in a book to which I called your readers' attention a few weeks ago. Schilling there remarks that absolute counts were proposed by Naegeli and others, but he discourages them in clinical work on the ground that they are obtained by combining two estimations (total and differential), neither of which is perfectly accurate, so that the results are the less certain. Moreover, the calculations involved will retard the receipt of the blood count, which the clinician wants as soon as possible as conditions change so quickly. There is another point. The absolute expression of the white cells sometimes makes the result of relative changes less apparent; Schilling instances the small relative neutrophilia of acute tubercle whether the total leucocytes are many or few, the relative monocytosis of malaria, and the persistently high relative

Obituary.

WILLIAM SMITH KERR, M.B., F.R.C.S. EDIN.

THE sudden death of Mr. W. S. Kerr deprives the medical profession in Sheffield of one of its most able members. The son of a doctor—William Smith Kerr, M.D., of Dumfries—he was born in 1869 and educated at Dumfries Academy and the University of Edinburgh. Graduating as M.B. in 1890 he returned to his own town as house surgeon to the Dumfries and Galloway Royal Infirmary, whence he found his way to Sheffield in 1891. At the Sheffield Royal Infirmary he remained as house surgeon, junior and senior, until 1895, when

he resigned and started practice in Brookhill. Not long afterwards he joined the late Mr. Harry Lockwood in general practice, and after obtaining the Fellowship of the Royal College of Surgeons of Edinburgh in 1903 he was appointed by the infirmary authorities to found and take charge of the ear, nose, and throat department. Up to this time such work had been done by the general surgeons, but Kerr soon created a large out-patient department and found him-

self cramped for want of in-patient beds. As a reward of his untiring service and skill he lived to see a splendid block—the Princess Mary block—built for his special surgery, and there he worked during his last three years.

"He was honoured and most beloved," writes a medical friend, "because the foundation-stones upon which his character was built were devotion to duty and devotion to his fellow men. His was a personality brimming over with goodwill and kindly sympathy, which compelled the affection of everyone who knew him. No professional colleague ever spoke of him but in terms of sincere affection, and no patient ever thought of him but as a friend in time of need. It was perhaps in his dealing with children that this side of his character was most evident. No one who had witnessed the way in which he could win the confidence of a child and dispel all fear could fail to see that a great love of his fellows was the source of his power. Anything selfish in word and deed was completely foreign to his nature, and to those who knew him inconceivable. He was, moreover, firm and resolute in any course which he thought to be right and devoted heart and soul to his specialty. Quite apart from their personal regard his skill and efficiency were such as to command the complete confidence of colleagues and patients alike."

At the outbreak of war Mr. Kerr joined the Sheffield City Battalion as its first medical officer, but was subsequently transferred to the 23rd West Riding Light Ambulance, which he commanded in France.

He returned home on account of ill-health, but became successively inspector of ambulances in the Eastern Counties and surgeon specialist to the 4th Northern General Hospital. He married Edith, daughter of Dr. C. S. Blythman.

FRANCIS WASHINGTON EVERARD HARE,
M.D. DURH.

Dr. Francis Hare, who died at Beckenham on Dec. 9th after six days' illness, was a recognised authority on alcoholism, and had devoted nearly 30 years to the study of this addiction. Born at Dublin in 1858, the son of Matthias Hare, LL.D., he was educated at Fettes, and went to London as a medical student, first at St. Mary's and later at St. Thomas's Hospital. Taking the diploma of M.R.C.S. in 1879 he gained post-graduate experience at Newcastle Royal Infirmary, and graduated as M.B. Durh. in 1884, proceeding to the M.D. degree seven years later. After serving for some time as a ship's surgeon he settled in Queensland, Australia, where he was appointed medical superintendent of Charters Towers District Hospital, and acted for a time in the same capacity at Brisbane General Hospital. In course of time he became a consulting physician to the latter institution, and he also held the office of inspector-general of hospitals for the State. Although he did a considerable amount of general surgery and ophthalmic work in Australia, his chief interest lay in medicine, and when in 1904 he came home on grounds of health he found a congenial opening for his abilities in the post of medical superintendent of Norwood Sanatorium. This institution moved to Beckenham in 1909, and Hare was associated with it until three years ago. At this time he was in poor health; nevertheless he started a nursing home in Beckenham where with a colleague he was able to carry on the work to which he had been so long devoted. A pioneer in his specialty he was the author of a standard text-book on the clinical aspects and treatment of alcoholism, which was published in 1915. His knowledge and experience were wide, and where patients were concerned he was indefatigable and did not recognise defeat. A medical friend writes of him that he never complained of his own suffering, which was often intense, but always carried on, "his one interest being a successful cure or an improvement in a new patient. He was a man who made few friends, but his friendship was an invaluable one."

Dr. Hare married, in 1902, Ethel Maud, daughter of George Theodore Bell, of Brisbane.

JOHN McASKILL HENDERSON, M.B. EDIN.,
D.Sc. ABERD.

Dr. J. M. Henderson, who died at Nairobi on Nov. 22nd, was born in Ayr in 1895, and had a distinguished career in the University of Edinburgh, where he graduated in arts, science, and medicine. He was prominent in the social life of the University, and was for varying periods president of the S.R.C., the Union, and of the Celtic Society. During the war he was employed as a chemist in a munition factory, having been rejected for military service. He graduated as M.B. in 1922, and after engaging for some time in general practice in Glasgow decided to take up research as a career. He went to the Rowett Institute at Aberdeen at the end of 1923 and studied the effects of ultra-violet light on metabolism and on problems connected with lactation. He had just begun to work on the metabolism of iodine when he went out to Kenya, along with other medical and agricultural graduates from Aberdeen, in charge of the medical team conducting an inquiry into nutritional problems in that colony. His work there was characterised by the same enthusiasm, thoroughness, and sound judgment as he had shown at Aberdeen, and it has thrown a new light on many problems concerning the health of the native. He had just wound up his experiments and was about to leave for

absurd to advocate the conservation of heat and also the exposure of the feet to cold. But physiology teaches that in *health* exposure to cold, especially when accompanied with muscular exercise, stimulates the circulation and increases metabolism throughout the body. For this reason walking barefoot in the grass may be beneficial for chilly persons. But all depends on the reaction produced. Cold, as a provocative of heat, must be used in measured doses. To obtain good results, not only the feet but the whole body must be warmed by the cold. There is a saying that "to maintain an agreeable warmth of the skin is one of the great secrets of health." To this I would add that those who keep their feet warm seldom suffer from chills or consequent catarrhs. I should like to know if this is a general experience.

I am, Sir, yours faithfully,

R. FORTESCUE FOX.

Devonshire-place, W, Dec. 6th, 1928.

SHOT IN THE VERMIFORM APPENDIX.

To the Editor of THE LANCET.

SIR,—The cases reported by Prof. John Fraser and others in your columns (THE LANCET, Dec. 1st and 8th) recall to my mind a patient admitted to the North Staffordshire Royal Infirmary on July 27th, 1926.

He gave a history of vague discomfort in the right iliac fossa, occasionally exaggerated into attacks of acute pain resembling renal colic and associated with frequent micturition and the passage of blood in the urine. Microscopic examination of the urine by his own doctor revealed an excessive number of *Bacillus coli*, with which diagnosis he was admitted to the North Staffordshire Royal Infirmary. Radiography showed a long, opaque outline in the region of the appendix (see figure), which caused considerable

doubt as to whether it was due to a calculus in the ureter or a solid concretion in the appendix. Opinion was divided, but the radiologist, Dr. A. H. John, of Stoke-on-Trent, was certain that the shadow was external to the line of the ureter. There was only a slight tenderness on deep palpation, and Bastedo's sign was persistently negative. There was no leucocytosis.

An operation was performed by Mr. George Blair on August 6th. The appendix was found free and successfully removed, and on section showed it to contain 42 pellets similar to those in the case reported by Prof. John Fraser. Recovery was uneventful, and the patient was discharged on August 23rd, 1926, to his work as a gentleman's chauffeur.

It was ascertained that in his capacity as chauffeur this man was often utilised as a beater, and was, accordingly, privileged to receive many gifts of game; and in no other way could he account for the swallowing of pellets than by the rapid bolting of his food. It is interesting that the symptoms he complained of were suggestive of an inflammatory condition of the urinary tract rather than trouble in the appendix. Since the operation his health has remained good, and no further pain on micturition and no further blood in the urine has been noted.

I am, Sir, yours faithfully,

A. WILSON GILL.

Hanley, Stoke-on-Trent, Dec. 13th, 1928.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are notified:—Surg. Comdrs: J. D. Murphy to *Courageous*; J. C. Sinclair to *Birmingham*; B. R. Bickford to *Vivid*; W. G. Thwaytes to *Nelson*; J. G. Danson to *President* for three months' post-graduate course; H. L. P. Peregrine to *Adventure*; C. F. O. Sankey to *Victory*; A. A. Sanders to *Benbow*; J. M. Horan to *Vulcan*; J. F. M. Campbell to *Berwick*; A. G. Malcolm to *Egmont*; M. J. Aitken to *Cardiff*; and J. G. Boal to *Tarar*.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Lt. H. P. Widdup is confirmed in his rank.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lt.-Cols. retire on ret. pay: P. C. Douglass, B. R. Dennis, and C. A. J. A. B. Foote.

The undermentioned Majrs. to be Lt.-Cols.: G. G. Tabuteau, vice Lt.-Col. P. C. Douglass, to ret. pay, and J. M. B. Rahilly, vice Lt.-Col. B. R. Dennis, to ret. pay.

ARMY DENTAL CORPS.

Maj. J. G. Worsley, having attained the age limit of liability to recall, ceases to belong to the Rcs. of Off.

ARMY RESERVE OF OFFICERS.

A. W. Davidson to be Lt.

TERRITORIAL ARMY.

Col. J. G. Martin vacates the appt. of A.D.M.S. 53th (W. Lan.) Div.

Lt.-Col. (Bt. Col.) D. C. L. Orton, from Gen. List, R.A.M.C., to be Col., and to be A.D.M.S. 53th (W. Lan. Div.).

Capt. N. F. C. Burgess to be Capt.

ROYAL AIR FORCE.

The undermentioned Flight Lts. are transferred to the Reserve, Class Dii: E. A. Aslett and W. Parsons.

Temp. Capt. A. R. H. Bennett (General List, Army, Dental Surgeon) is granted a temporary commission as a Flight Lt. on attachment to the R.A.F.

Flight Lt. H. J. Procter is promoted to the rank of Squadron Leader (Dental) on promotion to the rank of Major in the Army Dental Corps.

The undermentioned Flying Officers (Temp. Lts., General List, Army) are promoted to the rank of Flight Lts. (Dental) on promotion to the rank of Temp. Capt. in the Army: H. I. Clapperton and A. P. McClare.

RESERVE OF AIR FORCE OFFICERS.

Flight Lt. L. Game resigns his commission on appointment to a commission in the Royal Army Medical Corps.

Flight Lt. B. C. W. Pasco relinquishes his commission on completion of service.

INDIAN MEDICAL SERVICE.

Capt. Homi Rustomji Cursetji to be Maj.

Lt.-Col. J. B. D. Hunter retires.

Temp. Capt. Bhagat Ram Tandon relinquishes his temp. commission and retains his rank.

COLONIAL MEDICAL SERVICES.

The following appointments have been made by the Secretary of State for the Colonies during the month of November: C. Burnett, J. Crawford, C. S. Davies, and W. C. Dale, medical officers, West African Medical Staff; R. A. McNab and C. H. Swapp, medical officers, Straits Settlements.

ROYAL ARMY MEDICAL COLLEGE.

The following prizes have been awarded to officers of the last junior officers' class at the Royal Army Medical College, London:—

Herbert Prize (for highest aggregate) and First Montagu Prize in Military Surgery: Lieut. E. S. Lucas, I.M.S., St. Thomas's. Second Montagu Prize in Military Surgery: Lieut. G. L. Grievie, R.A.M.C., Glasgow University. Russell Martin Prize in Tropical Medicine: Lieut. M. R. Stoddart, I.M.S., Cambridge and St. Bartholomew's. Parker Memorial Prize in Hygiene: Lieut. G. L. Grievie, R.A.M.C., and Lieut. H. W. Farrell, I.M.S., University College, Dublin (ex aequo). Talloch Memorial Prize in Pathology: Lieut. A. T. H. Marsden, R.A.M.C., Durham University. Favre Memorial Prize in Pathology: Lieut. V. L. M. Lee, I.M.S., Royal College of Surgeons, Ireland. Marshall Webb Prize (medical administration): Lieut. A. T. H. Marsden, R.A.M.C.

Obituary.

WILLIAM SMITH KERR, M.B., F.R.C.S. EDIN.

THE sudden death of Mr. W. S. Kerr deprives the medical profession in Sheffield of one of its most able members. The son of a doctor—William Smith Kerr, M.D., of Dumfries—he was born in 1869 and educated at Dumfries Academy and the University of Edinburgh. Graduating as M.B. in 1890 he returned to his own town as house surgeon to the Dumfries and Galloway Royal Infirmary, whence he found his way to Sheffield in 1891. At the Sheffield Royal Infirmary he remained as house surgeon, junior and senior, until 1895, when

he resigned and started practice in Brookhill. Not long afterwards he joined the late Mr. Harry Lockwood in general practice, and after obtaining the Fellowship of the Royal College of Surgeons of Edinburgh in 1903 he was appointed by the infirmary authorities to found and take charge of the ear, nose, and throat department. Up to this time such work had been done by the general surgeons, but Kerr soon created a large out-patient department and found him-

MR. W. S. KERR.

self cramped for want of in-patient beds. As a reward of his untiring service and skill he lived to see a splendid block—the Princess Mary block—built for his special surgery, and there he worked during his last three years.

"He was honoured and most beloved," writes a medical friend, "because the foundation-stones upon which his character was built were devotion to duty and devotion to his fellow men. His was a personality brimming over with goodwill and kindly sympathy, which compelled the affection of everyone who knew him. No professional colleague ever spoke of him but in terms of sincere affection, and no patient ever thought of him but as a friend in time of need. It was perhaps in his dealing with children that this side of his character was most evident. No one who had witnessed the way in which he could win the confidence of a child and dispel all fear could fail to see that a great love of his fellows was the source of his power. Anything selfish in word and deed was completely foreign to his nature, and to those who knew him unchangeable. He was, moreover, firm and resolute in any course which he thought to be right and devoted heart and soul to his specialty. Quite apart from their personal regard his skill and efficiency were such as to command the complete confidence of colleagues and patients alike."

At the outbreak of war Mr. Kerr joined the Sheffield City Battalion as its first medical officer, but was subsequently transferred to the 22nd West Riding Field Artillery, which he commanded in France.

He returned home on account of ill-health, but became successively inspector of ambulances in the Eastern Counties and surgeon specialist to the 4th Northern General Hospital. He married Edith, daughter of Dr. C. S. Blythman.

FRANCIS WASHINGTON EVERARD HARE, M.D. DURH.

Dr. Francis Hare, who died at Beckenham on Dec. 9th after six days' illness, was a recognised authority on alcoholism, and had devoted nearly 30 years to the study of this addiction. Born at Dublin in 1858, the son of Matthias Hare, LL.D., he was educated at Fettes, and went to London as a medical student, first at St. Mary's and later at St. Thomas's Hospital. Taking the diploma of M.R.C.S. in 1879 he gained post-graduate experience at Newcastle Royal Infirmary, and graduated as M.B. Durh. in 1884, proceeding to the M.D. degree seven years later. After serving for some time as a ship's surgeon he settled in Queensland, Australia, where he was appointed medical superintendent of Charters Towers District Hospital, and acted for a time in the same capacity at Brisbane General Hospital. In course of time he became a consulting physician to the latter institution, and he also held the office of inspector-general of hospitals for the State. Although he did a considerable amount of general surgery and ophthalmic work in Australia, his chief interest lay in medicine, and when in 1904 he came home on grounds of health he found a congenial opening for his abilities in the post of medical superintendent of Norwood Sanatorium. This institution moved to Beckenham in 1909, and Hare was associated with it until three years ago. At this time he was in poor health; nevertheless he started a nursing home in Beckenham where with a colleague he was able to carry on the work to which he had been so long devoted. A pioneer in his specialty he was the author of a standard text-book on the clinical aspects and treatment of alcoholism, which was published in 1915. His knowledge and experience were wide, and where patients were concerned he was indefatigable and did not recognise defeat. A medical friend writes of him that he never complained of his own suffering, which was often intense, but always carried on, "his one interest being a successful cure or an improvement in a new patient. He was a man who made few friends, but his friendship was an invaluable one."

Dr. Hare married, in 1902, Ethel Maud, daughter of George Theodore Bell, of Brisbane.

JOHN McASKILL HENDERSON, M.B. EDIN., D.Sc. ABERD.

Dr. J. M. Henderson, who died at Nairobi on Nov. 22nd, was born in Ayr in 1895, and had a distinguished career in the University of Edinburgh, where he graduated in arts, science, and medicine. He was prominent in the social life of the University, and was for varying periods president of the S.R.C., the Union, and of the Celtic Society. During the war he was employed as a chemist in a munition factory, having been rejected for military service. He graduated as M.B. in 1922, and after engaging for some time in general practice in Glasgow decided to take up research as a career. He went to the Rowett Institute at Aberdeen at the end of 1923 and studied the effects of ultra-violet light on metabolism and on problems connected with lactation. He had just begun to work on the metabolism of iodine when he went out to Kenya, along with other medical and agricultural graduates from Aberdeen, in charge of the medical team conducting an inquiry into nutritional problems in that colony. His work there was characterised by the same enthusiasm, thoroughness, and sound judgment as he had shown at Aberdeen, and it has thrown a new light on many problems concerning the health of the native. He had just wound up his experiments and was about to leave for

Aberdeen to see to the publication of his results when he contracted the disease that proved fatal to him. While his results remain as a contribution to medical science, the ideas derived from them by a foreseeing and constructive mind lie buried with him. He was always able to express these ideas in precise and lucid English, and his ability as a speaker will be long remembered. A man of wide interests and a broad mind, he was well versed in literature, music, and art, and was himself no mean draughtsman. His ready wit, his great fund of anecdotes, and amiable personality will be missed in the many social gatherings he attended. He leaves a widow.

JOSEPH PRIESTLEY, M.D. EDIN., D.P.H.

THE sudden death of Dr. Joseph Priestley on Dec. 15th came as a shock to his many friends. It is only a few months since the expression of keen regret on the part of all sections of the community at his enforced retirement by age-limit from the position of medical officer of health of Lambeth which he had worthily held for the long period of 32 years. These

DR. J. PRIESTLEY.

expressions of regret were accompanied by quite an unusual number of valuable presentations, and one from the medical practitioners of Lambeth gave especial pleasure to the recipient and indicated the very good feeling which always existed between Dr. Priestley and his colleagues.

Joseph Priestley was a direct descendant of the famous theologian and man of science whose name he bore. He was already a graduate

in arts of London University before he went to Edinburgh for his medical course. In 1883 he took his M.B. Edin., with a gold medal in medical jurisprudence and a prize in public health, and three years later his thesis for the M.D. was commended. After qualification Priestley obtained a wide range of clinical experience, for he was house surgeon to the Manchester Royal Infirmary, clinical assistant at Brompton, Great Ormond-street, and the Royal Westminster Ophthalmic Hospitals, and interne at the Rotunda. For a while he was in practice at Twickenham where he acted as medical referee to a number of insurance societies, was medical officer to Bath House School, and lectured for the St. John Ambulance Association. After a period as assistant medical officer of health at Camberwell he was appointed medical officer and public analyst to the Borough of Leicester. When he came to Lambeth Dr. Priestley had accordingly already made his mark as an outstanding sanitarian by his good work in Leicester in a similar position, and his energetic advocacy of environmental hygiene, and especially his crusade against the abominations of the so-called conservancy system, accepted at that time as inevitable, must be fresh in the recollection of many residents of that city. For many years Dr. Priestley took an active and leading part in the work of the Royal Sanitary Institute, and for at least two decades he was one of the secretaries of the Society of Medical Officers of Health. He was a foreign member of the Société d'Hygiène.

During his tenure of office at Lambeth Dr. Priestley saw many changes in the nature of the public health services, as was natural owing to the greater attention given nowadays to the individual, and he showed in his final report for 1927 (reviewed in another column) how a large staff could gradually be built up, and the remarkable contrast between the present mortality statistics and those of 1895, when he was first appointed to the parish of St. Mary's, Lambeth. Among his more noteworthy writings is a report on the physical condition of the working classes (1912), and articles on house drainage, infantile mortality, and small-pox epidemics in ill-vaccinated communities. Dr. Priestley left Lambeth in a very much better sanitary condition than he found it. This is not the place to attempt to evaluate the effect of the various public health measures he introduced. The verdict of his compeers is that Joseph Priestley was an able and hardworking leader in a hygienic movement which has resulted in great benefit to the health of London and that he had in large measure the gift of getting the reforms which he visualised translated into practice.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT BILLS: FINANCIAL RESOLUTIONS.

IN the House of Commons on Friday, Dec. 14th, the financial resolutions in connexion with the Local Government Bill and the Local Government (Scotland) Bill were agreed to on report.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 12TH.

Orthopaedic Treatment of School-children.

MR. THOMAS GRIFFITHS asked the President of the Board of Education whether, in view of the urgency for more beds for treatment for orthopaedic diseases in children from the elementary schools in Hampshire, he would consider payment of a grant on any further expenditure incurred to provide more beds over the 12 beds now allotted for this purpose by local generosity at the Trelow Cripples' Home at Alton.—Lord EUSTACE PERCY replied: The Hampshire Education authority are, I understand, examining the question of extending their arrangements for orthopaedic treatment for school-children in their area. I am prepared to consider sympathetically any proposals for such extension which the authority may see fit to formulate. Grant will be payable on expenditure for this purpose approved by the Board in the ordinary way.

Poor-law Authorities and Medical Treatment.

VISCOUNTESS ASTON asked the Minister of Health what amount the poor-law authorities had spent for each of the last three years for which figures were available on such treatment of the sick as would be transferred to the public health authorities under the Local Government Bill.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: I am afraid that exact figures are not available, but the approximate expenditure of poor-law authorities on the services mentioned in the question was £9,150,000, £9,530,000, and £10,160,000 in the years 1924-25, 1925-26, and 1926-27 respectively. These figures include expenditure on the maintenance of persons in poor-law institutions, for persons suffering from disease of body or mind, and in the sick and infirm wards of other poor-law institutions, and on domiciliary medical relief.

Lotteries for Hospitals.

COMMANDER BELLAIS asked the Home Secretary whether the Government would consider the question of issuing licences for lotteries in aid of hospitals, charities, &c., in view of the differences of police action in various parts of the country since various decisions in the High Court as to Lottery, Gaming, and Betting Acts.—Sir W. JOYNSON-HICKS replied: All public lotteries are unlawful, whether for charity or otherwise, and I have no authority to grant exemption from the law. This would require fresh legislation.

Road Accidents and the Provision of Mortuaries.

Mr. ALBERRY asked the Minister of Transport whether he was aware of the fact that the numerous fatal accidents resulting from the increased use of the roads were causing concern to many local authorities and parish councils who were without the use of any mortuary; and that it was becoming increasingly difficult to find suitable accommodation after such fatal accidents; and whether he had consulted with the Home Secretary and the Minister of Health with a view to issuing fresh regulations on this subject or to varying in any way the present instructions.—Mr. CHAMBERLAIN (Minister of Health) replied: Local authorities under the Public Health Act, 1875, have full powers to provide mortuaries, and where there is need for further accommodation representations should be made to the appropriate local authority. I am not aware that any instructions or regulations have been issued dealing with this matter.

Schools of Medicine and Women Students.

Sir ROBERT THOMAS asked the Minister of Health the number of schools of medicine in London and the rest of the country respectively from which women were excluded; and whether, in view of the increasing need of women with medical knowledge, he would set up an inquiry with a view to removing these restrictions.—Sir KINGSLEY WOOD replied: My right hon. friend has no official information on this matter, but he understands the position outside London to be that there is no restriction on the admission of women to medical schools. The position in London already forms the subject of an inquiry initiated by the University of London.

Dr. WATTS: Is it not a fact that the medical profession is already overcrowded and that there are many men who cannot find anything to do?

No answer was given.

THURSDAY, DEC. 13TH.

Silicosis and Workmen's Compensation.

Mr. DAVID GRINFELL asked the Home Secretary whether the regulations for granting compensation to men disabled by silicosis would provide for those cases where total disability had already been proved to be due to this form of occupational disease.—Sir W. JOYNSON-HICKS replied: No, Sir. I am advised that I should have no power under the Act to give this scheme any such retrospective application.

Poor-law Relief in Glamorgan.

Mr. GEORGE HALL asked the Minister of Health the number of persons in receipt of poor relief in the county of Glamorgan on the latest available date, and for the corresponding date for the years 1913, 1925, 1926, and 1927 respectively; and if he would give the figures for each poor-law union separately.—Mr. CHAMBERLAIN replied: The following is the table asked for:—

Name of poor-law union.	Number of persons in receipt of poor-law relief (excluding lunatics in asylums, casuals, and persons in receipt of domiciliary medical relief only) on the last Saturday in November.				
	1913.	1925.	1926.	1927.	1928.
Bridgend and Cowbridge	1,878	9,904	33,313	5,070	4,588
Cardiff	5,090	13,521	18,575	13,878	11,314
Gower	210	360	918	356	361
Merthyr Tydfil	4,080	22,018	65,077	12,621	14,424
Neath	3,027	10,297	29,191	8,662	8,152
Pontardawe	704	1,174	7,422	1,289	1,308
Pontypridd	6,903	30,180	82,389	18,307	20,337
Swansea	3,025	6,057	14,596	8,195	6,457
Totals for Union County of Glamorgan	25,547	93,511	251,481	68,378	66,941

School Dental Service in Wales.

Sir ROBERT THOMAS asked the President of the Board of Education what was the number of schools in Wales which had a dental service; how many dentists were employed; the number of children who had their teeth inspected during the last school year; the number who received treatment; and the estimated total cost.—Lord EUSTACE PERCY replied: I am unable to state the number of schools in Wales which have a dental service, but the number of children who have had their teeth inspected is 27,000 out of a total of 50. The number of dentists employed

is 45. The number of children dentally inspected during 1927 was 162,605, and the number treated 68,345. The total cost of the salaries of the school dentists was, approximately, £18,000, and additional expenditure was incurred for travelling expenses, premises, equipment, dental attendants, &c.

Grants for Maternity and Child Welfare.

Mr. BRIGGS asked the Minister of Health what was the amount of the grants given last year for maternity and child welfare.—Mr. CHAMBERLAIN replied: The amount of the grants for maternity and child welfare paid in the last financial year out of the vote for the Ministry of Health was, approximately, £1,040,000, including about £16,000 in respect of the training of midwives and health visitors.

Mr. BRIGGS: Would my right hon. friend welcome the receipt of further money from the Treasury for these purposes?—Mr. CHAMBERLAIN: Yes, I should always welcome money from the Treasury for these grants.

Mr. MARCH: Has the right hon. gentleman given notice to any of these maternity and child welfare centres to reduce the amount they are now allowed for expectant mothers?—Mr. CHAMBERLAIN: No distinction is drawn.

Government Grant to Cambridge University.

Sir HARRY BRITAIN asked the Chancellor of the Exchequer whether it was proposed to offer the University of Cambridge a grant towards the sum required to enable it to accept the offer of the International Education Board of the Rockefeller Foundation; and, if so, of what amount.—Captain BOWYER replied: The Government have decided to offer to the University a grant of £50,000 subject, of course, to the provision of funds by Parliament. They believe that the highest national as well as imperial and international interests demand that the great scheme made possible by the generous benefaction of the International Education Board should be fully carried into effect for the advancement of agriculture and of the fundamental sciences on which agriculture depends.

Caseous Lymphadenitis in Imported Mutton.

Mr. WILLIAM THORNE asked the Minister of Health the terms of the clauses in the Foreign Meat Regulations dealing with the disease of caseous lymphadenitis in imported mutton, and the instructions to inspectors of meat and food when carcasses were found to be infected; and whether the whole carcass or only the affected parts had to be destroyed.—Mr. CHAMBERLAIN replied: The effect of Articles 7, 8, and 9 of the Public Health (Imported Food) Regulations is that the medical officer of health of a port, or riparian sanitary authority, may examine imported meat and apply to a justice to order its condemnation if he is of opinion that it is diseased, or unsound, or unwholesome, or unfit for human consumption. A memorandum issued by my department as to the criteria to be adopted in the inspection of meat recommends the condemnation of the entire carcass and all the organs if evidence of caseous lymphadenitis is found.

MONDAY, DEC. 17TH.

Sickness among Women Clerks.

Miss BONDFIELD asked the Minister of Health what was the average number of days sick leave per head per annum taken by women in the writing assistant, typing, and clerical grades, respectively, in the Ministry of Health during the years 1925, 1926, and 1927; and what was the average number of days sick leave per head per annum in the case of each grade concerned taken on account of nervous troubles.—Mr. CHAMBERLAIN replied: The average number of days sick leave per head per annum taken by women in the writing assistant, typing, and clerical grades, respectively, in my department, during the years 1925, 1926, and 1927, was as follows:—

	1925.	1926.	1927.
Writing assistants	12.8	9.5	10.5
Typing staff—			
(a) Established	19.0	16.6	13.6
(b) Unestablished	13.9	10.2	13.2
Clerical Officers	15.2	11.8	13.9

I regret that I am unable to give the information asked for in the last part of the question, as it could not be obtained without an undue amount of time and labour.

Miss BONDFIELD asked the President of the Board of Education what was the average number of days sick leave per head per annum taken by women in the typing and clerical grades, respectively, in the Board of Education during the years 1925, 1926, and 1927; and what was the

average number of days sick leave per head per annum in the case of each grade concerned taken on account of nervous troubles.—Lord EUSTACE PERCY replied: The answer to the first part of the question is contained in the following statement:—

Leave year ending—		Days per head per annum.
Jan. 31st, 1926 ..	{ Clerical ..	14.6
	{ Typing ..	13.1
Jan. 31st, 1927 ..	{ Clerical ..	10.7
	{ Typing ..	10.6
Jan. 31st, 1928 ..	{ Clerical ..	12.5
	{ Typing ..	8.5

With regard to the second part of the question, the information asked for is not available.

Street Accidents to Children.

Mr. DAY asked the Home Secretary the number of street accidents to children for the 12 months ended to the last convenient date.—Sir V. HENDERSON (Under Secretary to the Home Office) replied: I can only give the figures for London (Metropolitan Police District and City of London). The figures for the 12 months to Sept. 30th last are: killed 238, and injured 10,877.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation on Dec. 17th the following degrees were conferred:—

D.M.—A. Q. Wells.

B.M.—G. G. Hill, J. C. Neely, Joyce Wright, and Margaret A. L. Herbertson.

UNIVERSITY OF LONDON.—At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B., B.S.

Honours.—G. W. Ayres (d), St. Mary's Hosp.; Elizabeth Cooper (b), London (R.F.H.) School of Medicine for Women; H. P. Himsworth (a, b, c, University Medal), Univ. Coll. Hosp.; C. A. Keele (a), Middlesex Hosp.; G. W. Rake (a, d), Guy's Hosp.; and R. W. Reid (b, d), St. Thomas's Hosp.
(a) Distinguished in medicine; (b) in pathology; (c) in surgery; (d) in midwifery.

Pass.—S. I. Abrahams, Guy's Hosp.; G. T. Allerton, London Hosp.; Sophia Antonovitch, London (R.F.H.) School of Medicine for Women; Harris Avery, Charing Cross Hosp.; Olwen R. Binyon, St. Mary's Hosp.; G. W. Black, Middlesex Hosp.; G. N. Box, St. Thomas's Hosp.; Marjorie F. Brierley, Univ. Coll. Hosp.; Emily E. Cass and Stuart Craddock, St. Mary's Hosp.; W. P. M. Davidson, St. Bart's Hosp.; John Davies, Westminster Hosp.; S. J. M. De Navasquez, Guy's Hosp.; Irene Dixon, Charing Cross Hosp.; Marjorie M. Dobson, London (R.F.H.) School; C. P. Donnison, London Hosp.; Elsie M. Douglas, Univ. Coll. Hosp.; David Ellis, Guy's Hosp.; Alexandra G. H. English, London (R.F.H.) School; M. R. Ernst, St. Bart's Hosp.; Horace Evans, London Hosp.; Geraldine W. Everett, London (R.F.H.) School; A. P. Farmer, St. Thomas's Hosp.; A. McK. Fleming, Middlesex Hosp.; G. G. Gillam, Univ. Coll. Hosp.; Helen M. Herbert and Alice D. M. Hodge, London (R.F.H.) School; Muriel S. Hulke, Univ. Coll. Hosp.; Philip Inwald, Middlesex Hosp.; I. J. Jones, St. Thomas's Hosp.; R. M. Jones and D. F. Kannar, Guy's Hosp.; E. M. Lourie, Univ. Coll. Hosp.; Samuel McGladdery, St. Bart's Hosp.; Murdo Mackenzie, Guy's Hosp.; Hugh Mannington, Middlesex Hosp.; W. H. Miller, Guy's Hosp.; M. B. Mody, Univ. Coll. Hosp.; C. F. Moore, St. Bart's Hosp.; G. E. B. Payne and Mary E. Pease, Univ. Coll. Hosp.; David Preiskel, St. Bart's Hosp.; Morris Rothkopf, Middlesex Hosp.; Clarice A. Skidmore and C. F. J. Smith, St. Mary's Hosp.; Edith J. L. Smith, London (R.F.H.) School; E. R. Smithard, Middlesex Hosp.; Eileen R. B. Snow, London (R.F.H.) School and St. Mary's Hosp.; J. G. Thwaites, St. Thomas's Hosp.; Phyllis D. Towell, London (R.F.H.) School; Scott-Russell Trick, Guy's Hosp.; Gladys M. Tullidge, London (R.F.H.) School and St. Mary's Hosp.; A. G. Watkins and A. R. N. Whitlow, Univ. Coll. Hosp.; P. C. Wickremesinghe, Guy's Hosp. and Ceylon Med. Coll.; L. A. Willmott, St. Bart's Hosp.; Jessie Wiltshire, Univ. Coll. Hosp.; Elsie E. Wright, St. Mary's Hosp.; and Winifred M. Wright, London (R.F.H.) School.

The following have passed in one of the two groups of subjects:—

Group I.—Nancy M. Badeley, London (R.F.H.) School; S. W. Barber, St. Bart's Hosp.; Annie G. Busher and Beatrice A. Butterworth, London (R.F.H.) School; K. J. H. Davies, Guy's Hosp.; Hilda C. Dean, Charing Cross Hosp.; C. J. Donelan, St. Bart's Hosp.; Mark Footerman, Univ. Coll. Hosp.; A. P. Gaston, St. Bart's Hosp.; H. N. W. Harley, Guy's Hosp.; Kathleen Horne, Univ. of Leeds; Philip Kaplin, St. Mary's Hosp.; G. H. Livingstone, King's Coll. Hosp.; J. F. Mackenzie, Guy's Hosp.; K. W. Mackie, St. Bart's Hosp.; Hermia M.

Mills, London (R.F.H.) School; M. L. Mistri, Grant Med. Coll., Bombay, and Guy's Hosp.; Doreen G. C. Nix, Univ. of Bristol; Joan M. Oldaker, London (R.F.H.) School; and S. A. Wickramasinghe, Ceylon Med. Coll. and St. Bart's Hosp.

Group II.—Lucy E. Arthur, London (R.F.H.) School; John C. H. Avery, St. Mary's Hosp.; E. C. B. Butler, London Hosp.; E. O. Harris, Middlesex Hosp.; Dorothy P. Bryer, London (R.F.H.) School; J. V. Macgregor, Univ. Coll. Hosp.; Joyce Morgan, Westminster Hosp.; D. T. R. Morris, Univ. Coll. Hosp.; C. B. Picken and H. W. A. Post, Guy's Hosp.; H. G. G. Robertson, St. Thomas's Hosp.; Elizabeth H. Scurfield, London (R.F.H.) School; E. J. J. Smith, St. Bart's Hosp.; P. A. M. Soutter, Westminster Hosp.; Frances J. Vinter, London (R.F.H.) School; W. H. S. Wallace, St. Thomas's Hosp.; A. J. Watson, Middlesex Hosp.; J. W. Wigg, E. A. Wood, and B. A. Young, Univ. Coll. Hosp.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Primary Examination for the Fellowship held from Dec. 4th to 14th, 188 candidates presented themselves and 45 were approved. The following are the names and medical schools of the successful candidates:—

A. Ali, M.R.C.S., Cairo and London; R. M. Alderton, London; M. A. E. Anous, M.B., Cairo and St. Mary's; E. T. Bannister, Univ. Coll.; J. H. B. Beal, Oxford and St. Bart's; F. Bicknell, Oxford and St. Thomas's; G. H. H. Booth, M.B., Manchester; G. N. Clark, M.B., Aberdeen; A. C. Copley, M.B., Cambridge and Guy's; D. Davidson, Univ. Coll.; J. R. Dogra, M.B., Lahore and Middlesex; L. P. J. Erans, Cambridge and St. Bart's; F. G. Fenton, M.B., Melbourne and Middlesex; M. L. Formby, M.B., Adelaide and St. Mary's; R. L. Forsyth, M.B., Dublin and Roy. Coll. Surg., Ireland; F. Forty, M.B., Univ. Coll. and Middlesex; A. C. Frazer, St. Mary's; T. Giblin, M.B., Melbourne and Middlesex; A. J. B. Goldsmith, Middlesex; R. Grainger, M.B., Belfast; J. I. Griffiths, M.B., Cardiff and King's Coll.; H. E. Harding, London; C. H. S. Harris, St. Bart's; A. Helmy, M.R.C.S., St. Thomas's and King's Coll.; T. V. Jacob, M.B., Bombay and King's Coll.; E. F. King, M.B., Bristol; R. J. G. Milner, B.Ch. Murray, Cambridge and St. Bart's; M. G. W. O'Connell and J. H. Peel, Oxford and Middlesex; King's Coll.; C. A. S. Rajasin, M.B., Durham; A. de W. Raml, M.B., Leeds; J. G. Sandrey, M.B., Belfast and Middlesex; G. V. Stephenson, M.D., London; N. C. Tanner, Bristol; T. Thornton, M.B., St. Andrews and St. Mary's; J. G. W. Wainwright, Cambridge and St. Bart's; J. G. W. Wainwright, St. Thomas's and St. Mary's; Middlesex.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial on Dec. 14th the following degrees were conferred:—

M.D.—A. M. Affleck, Henry Bulst, A. H. Campbell, J. L. Chisholm, J. E. C. Ellis, A. M. M. Grierson, S. E. Kirk (in absentia), D. R. Lewis, Neil Macleod, Rosemary M. Morris, H. A. Murray (in absentia), B. R. Nisbet, M. B. Paterson, Allison Ritchie, Archibald Ronald, Jessie C. B. Sym, A. B. Walker, John Ward, and Alexandra A. Warnock (in absentia).

* Highly commended for thesis. † Commended for thesis.
M.B., Ch. B.—G. M. Rober, Karro, James, Andrew, O. Taylor, and W. P. Wallace.
* With honours.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were successful:—

M.D.—T. A. Clarke, R. W. Eldridge, J. E. Howie, D. U. Owen, Helen Standing, and A. G. Wilkinson.

M.B. and Ch.B. with Honours.
Class II.—Elizabeth B. Robson, and E. L. Rubin.

FINAL EXAMINATION FOR M.B. AND Ch.B.
Part III.—A. E. Adams, N. J. Crawford, J. H. St. B. Cradock, A. Dala, J. E. Jones, L. de Jongh, Hilda M. G. MacMahon, Garry, J. S. Mather, C. T. Mercer, G. W. Molyneux, E. E. Prebble, Ivy H. Rowlands, G. A. Talwar-Jones, and F. J. Welton.

* With distinction in surgery.
Old Regulations, Part I.—A. Gardner, Teresa Lightbound, and R. G. Walker. Part II.—F. J. H. Crawford, and A. M. Russell.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B. AND Ch.B.
Alice M. Butterworth, I. M. Hughes, E. P. Johnson, J. S. Miller, J. W. Murray, Evelyn I. M. Sheppard, R. F. Stubbins.

Raymond Whitehead, R. T. Wimmer, and Frederick Wraith.

Forensic Medicine.—Leslie Bold, Christobel M. Hall, E. Z. Levy, A. S. McGowan, and Alan Taylor.

Hygiene and Preventive Medicine.—Leslie Bold, Christobel M. Hall, E. Z. Levy, A. S. McGowan, J. H. Pattysen, E. J. B. Sewell, and Alan Taylor.

Obstetrics and Surgery.—Mary I. C. Mackintosh, and Marian M. Reekie.

UNIVERSITY OF BIRMINGHAM.—At a congregation on Dec. 14th the following degrees were conferred:—

M.D.—H. P. Jameson.

M.B., Ch.B.—T. C. Dance, L. W. Downie, A. H. J. Jackson, T. W. Masters, M. K. Omar, Elizabeth S. Smith, and K. A. Thomas.

The Diploma in Dental Surgery has been awarded to Cyril Ford, C. E. Godfrey, E. S. Kench, W. R. E. Pickworth, and E. H. Sharp.

FINAL EXAMINATION FOR L.D.S.

C. Ford, C. E. Godfrey, E. S. Kench, W. R. E. Pickworth, and E. H. Sharp.

UNIVERSITY OF LEEDS.—At recent examinations the following candidates were successful:—

FINAL EXAMINATION FOR M.B. AND CH.B.

Part II.—T. G. Clarke, J. Donovan, L. B. Flather, H. T. Knowles, Margaret F. Robertson, and S. Simon.

Part III.—T. L. Owen, N. Pycroft, J. O. Terry, S. G. Bedford, S. Bregman, A. Dalby, J. Donovan, Dorothy Hulstead, C. R. Hiley, H. Hopkinson, W. E. L. Lawson, R. J. H. Raines, D. R. Riddell, Dorcen M. Robertshaw, and L. Smith.

• Second-class Honours.

FINAL EXAMINATION FOR B.Ch.D.

J. R. S. White.

D.P.H.

Fannie Hirst and W. A. D. Lawson.

D.P.M.

D. K. Bruce and D. Perk.

The West Riding panel practitioners' prize in medicine has been awarded to Trevor Lynn Owen.

ROYAL INSTITUTION.—On Tuesday, Jan. 29th, 1929, Prof. J. S. Huxley will give the first of six lectures on Evolution and the Problem of Species. The lectures on subsequent Thursdays include three by Sir William Bragg on the Early History of X Rays.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS. Owing to the expiration of the lease of 28, Bedford-square, W.C., the offices of this organisation, including the Central Bureau of Hospital Information and the editorial office of the *Hospital Gazette*, are being transferred on Dec. 27th to Sentinel House, Southampton-row, London, W.C. 1. Tel.: Museum 8310.

ROYAL SANITARY INSTITUTE.—The following sessional meetings will be held at the Institute, 90, Buckingham Palace-road, London, S.W.: On Tuesday, Jan. 8th, 1929, at 5.30 p.m., Prof. Bostock Hill will open a discussion on Cleanliness: Is It the Basis of Health. On Friday, Feb. 1st, at 5 p.m., Major F. R. Humphreys will open a discussion on The Civilian Population and Chemical Warfare. Both of these sessional meetings will be held at the Institute, 90, Buckingham Palace-road, London, S.W.

DONATIONS AND BEQUESTS.—Miss Mary Caroline Hensley, Tindon, Sussex, who left £12,130, besides other bequests, left the residue of her property to the London Hospital.—Mr. Sydney Frank Stott, of Woodleigh, Cheshire, left £1600 to Oldham Royal Infirmary and after various personal bequests the residue of the estate, amounting to over £10,000, also to the infirmary.—Mr. Thomas Kirk, of Oaklea, Norton, Stockton-on-Tees, Durham, left £1250 to the Stockton and Thornby Hospital to endow a bed for the use, as far as possible, of workmen of the Carlton Iron Company, Ltd., and £250 to St. Dunstan's Home for Blind Soldiers.—Miss Mary Jane Kelle, Tulse Hill, London, S.E., left £12,600 for charities. The testatrix gave £1000 each to Guy's Hospital, the London Hospital, and St. Bartholomew's Hospital, and four other institutions; £500 to the Royal Hospital for incurables, Putney; and £250 each to the Royal Eye Hospital, Southwark, the Royal Blind Pension Association, the Royal National Orthopaedic Hospital, and at Newcastle, Perth, left £1500 to the County and City of York, Royal Infirmary, and £100 to the Ross Memorial Hospital, Birmmham.

The death is announced of Mr. J. Langford Moore, F.C.S., pharmacist to St. Bartholomew's Hospital. A memorial service was held in the Church of St. Bartholomew-the-Less on Dec. 19th.

A RAILWAY MEMORIAL HOSPITAL.—A hospital in memory of the old boys of the Southern Railway Servants' Orphanage at Woking is being erected in the grounds of the institution.

GRANTS FROM KING EDWARD'S FUND.—At a meeting of the general council of the Fund yesterday week it was decided to distribute £257,452, which includes ordinary maintenance grants, grants towards capital expenditure, and special pensions grants. Adding the final distribution out of the Wells legacies in May last, the grand total distributed to hospitals in 1928 is £288,202, besides £2000 to convalescent homes.

MEDICO-LEGAL SOCIETY.—The annual dinner of this Society was held at the Holborn Restaurant on Dec. 14th, with Sir William Willcox, the President, in the chair. In the absence of Earl Russell, the toast of "Medicine and Law" was proposed by Dr. F. G. Crookshank, who said that in listening to speakers at previous dinners he had sometimes doubted whether the toast was not "Medicine versus Law." It always interested him to hear lawyers referring to the British Medical Council and the General Medical Association, and he thought he might fairly retaliate by speaking of Sir Thomas Hughes, who was present that evening, as Chairman of the General Law Society or of the Bar Council Association. Sir Thomas Hughes, responding, repudiated the idea of any contest between medicine and law, which were sister professions, both concerned with doing their best for their fellow men. The doctor looked after their bodies and perhaps their souls, too, whilst the law looked after their character, property, and reputation. Medical victories had no shade of disappointment about them, since in medicine all were allied in fighting the common enemy. The lawyer, on the other hand, was always fighting someone else. Nevertheless, as Lord Bramwell had consolingly remarked: "In a long career at the Bar I have lost many cases I ought to have won, and won many cases I ought to have lost; and so on the whole justice is done." Dr. Walter Carr, President of the Medical Society of London, said it was the doctor's function to consider the well-being of his patients irrespective of laws and rules; whereas the lawyer had to put every possible obstacle in the way of arriving at a decision. Medical men would cheerfully sacrifice regulations to give their patient a chance of life, and perhaps they were too apt to follow the same course of action into spheres in which there was not the same urgency. Dr. Carr served with medical and legal colleagues on the committee of a charity and found that his medical friends were always ready to say: "Hang the standing orders." To which the lawyers replied: "You cannot hang a standing order; you can only suspend it; and you can only do that if due notice is given for one month and the decision is taken by two-thirds vote." The lawyer set great store by dates and would refuse a scholarship to a boy who by one day was born in the wrong year. Such a course seemed unjustifiable to medical men, who knew that the child's too early birth might well be due to the intervention of one of their colleagues anxious to have a night's rest. Mr. Justice Branson, proposing the toast of the "Medico-Legal Society," argued that there must always be a stile at which someone would stick. He held that there was much in common between the two professions, both of which were engaged in discovering the unknown from the known. Sir William Willcox, replying, said the Society was now in its twenty-sixth year and had gained 31 new members during the past 12 months. Eight meetings had been held and seven papers had been read, five by medical and two by legal members. The last had been given by Dr. Weatherly, now in his eightieth year, and had proved one of the best ever given to the Society. The discussions served a useful function in keeping members in touch with the modern developments of medicine and law, and this was very necessary since text-books were always several years out of date when they were published. Members also learned to know and appreciate one another, and doctors who belonged to the Society would find themselves well prepared for the ordeal of going into the witness-box. Lawyers required to be understood, and at a society like this the medical man would find himself beginning to understand them. Sir William concluded by referring to the valuable work done during the past year by the Hon. Treasurer (Sir Walter Schur-ler), the Hon. Secretaries (Sir Bernard Spilbury and Sir Ernest Goldard), and the Editors of the Society's *Transactions*. The toast of "The Guests" was proposed by Mr. Justice Humphreys and responded to by Sir Leonard Kershaw and Sir Malcolm Delevingne.

RESEARCH ON ASTHMA.—The Halley Stewart Trust has made a grant of £2500 to the Asthma Research Council for the establishment of special clinics at Guy's Hospital and the Hospital for Sick Children, Great Ormond-street, for research into the cause and treatment of asthma and allied diseases.

MEMORIAL TO THE LATE MR. GEORGE HEATON.—A new balcony to one of the children's wards at the General Hospital, Birmingham, has been presented to this institution by 11 nieces and nephews of the late Mr. George Heaton, who was hon. surgeon to the hospital from 1894 to 1919. It will be remembered that the late Mr. Heaton, who always took a deep personal interest in the General Hospital, left £1000 on trust for prizes in connexion with the medical and nursing staff.

THE PENSIONS MINISTRY AND ARTIFICIAL LIMBS.—According to the report of the Ministry of Pensions for the year 1927-28, the Ministry still has under its care more than 36,000 persons with artificial limbs. During the year 6311 limbs were supplied, most of them renewals; more than 51,000 limbs were repaired. The number of artificial legs was 5205, of which 3404 were light metal legs.

PRESENTATIONS TO MEDICAL MEN.—Mr. W. F. Haslam was recently presented with a silver tray and a cheque on his retirement from active service in the Birmingham Medical School. He has held a succession of offices since his appointment to the staff of the General Hospital in 1882 and was Dean of the Faculty of Medicine in the University of Birmingham from 1919 until his resignation in May of this year. The silver tray presented to him was inscribed as follows:—

"Presented (with a cheque) to William Frederick Haslam, M.B., F.R.C.S., by Colleagues and Friends in the University of Birmingham on his retirement from his office of Dean of the Faculty of Medicine, a token of affection and gratitude for valuable services to the Medical and Dental Schools and the University during a period of 46 years, 1882-1928."

Dr. James Allan Gray, who has been medical officer of health for Leith and medical officer and lecturer on clinical medicine to the Leith Hospital, has completed 50 years of practice in connexion with the town. To mark the occasion his fellow practitioners recently presented Dr. Gray with a barograph and a cheque.

THE LATE MISS EGLANTYNE JEBB.—Miss Jebb, co-founder and honorary secretary of the Save the Children Fund, who died at Geneva last Monday at the age of 52, was the eldest daughter of the late Mr. and Mrs. Arthur Trevor Jebb, of Ellesmere, and niece of the late Sir Richard Jebb, Regius Professor of Greek in the University of Cambridge. After leaving Lady Margaret Hall, Oxford, she trained as an elementary school teacher, and subsequently became a member of the Borough of Cambridge Education Committee. Her greatest work, however, was directed to the relief of suffering arising from war and untoward economic conditions. During the second Balkan War she visited Macedonia on behalf of the Macedonian Relief Fund, and towards the end of the late war she became one of the founders of the Fight-the-Famine Council. It was in this organisation that the Save the Children Fund had its genesis—a movement which has been the means of disbursing over £4,000,000 for the relief of child suffering. She it was also who drafted the Declaration of Geneva, laying down the minimal obligations of society to the child, which was adopted by the Assembly of the League of Nations in 1924. With the work of the League she was actively associated as an assessor to the Committee for Child Protection.

Appointments.

DIBLE, J. H., M.B., Ch.B. Glasg., M.R.C.P. Lond., has been appointed to the George Holt Chair of Pathology, University of Liverpool.

YORKE, WARRINGTON, M.D., Ch.B. Liverp., to the Alfred Jones Chair of Tropical Medicine, University of Liverpool.

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, Lake Hospital and Darnton House.—Res. Asst. M.O. £150.

Barbican General Hospital.—Jun. Res. S. £250.

Birmingham, Children's Hospital.—Cas. O. At rate of £250.

Blackburn C.—M.O.H. £600.

Burton, Der.—H.P. At rate of £150.

Cambridge—Laboratory.—John Lucas

Walker Studentship. £300.

Cancer Hospital, Fulham-road, S.W.—Radium Officer. £500.

Also Asst. S.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—Sen. and Jun. H.S.'s. At rate of £120 and £100 respectively.

Central London, Throat, Nose and Ear Hospital.—Two Hon. Asst. Out-patient Registrars.

City of London Hospital for Diseases of the Heart, &c., Victoria Park, E.—H.P. At rate of £100.

Colchester, Essex County Hospital.—H.P. £150.

Croydon General Hospital.—Hon. Jun. Physician.

Derbyshire Education Committee.—Asst. School M.O. £600.

Dumfries, Crichton Royal Mental Hospital.—Clin. Pathologist. £400.

Freemasons Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.

Golden—Hospital, W.—Hon. Surgeon.

Hull.—Res. M.O. £550.

Hull.—rate of £150.

Indian Medical Service.—Recruitment of European Officers.

Kingston and District Hospital.—Third Asst. Res. M.O. At rate of £250.

London Female Lock Hospital, 283, Harrow-road, W.—H.S. £150.

Births, Marriages, and Deaths.

BIRTHS.

LISTER.—On Dec. 16th, at Devonshire-place, W., the wife of Arthur Reginald Lister, M.C., F.R.C.S., of Bootham, York, of a daughter.

MARRIAGES.

DAVENPORT—MAYFIELD.—On Dec. 6th, at St. Bartholomew to the Great, E.C., Robert Cecil Davenport, F.R.C.S., to Helen Elizabeth Mayfield, M.R.C.S., L.R.C.P., eldest daughter of Mr. P. Mayfield and the late Mrs. Mayfield, of Hull.

DRU DRURY—HEWLINS CATLING.—On Dec. 12th, at St. Saviour's Church, Hampstead, Graham Dru Drury, M.R.C.S., L.R.C.P., to Helen Florence Hewlins Catling, youngest daughter of Mr. and Mrs. C. Brian Catling, of West Southbourne, Hants.

JOHNSON—PHILLMORE.—On Dec. 8th, at All Souls', Hampstead, Dr. Bernard R. M. Johnson to Olive Mary, only daughter of William and Violet Phillimore, of Hampstead.

KINGSFORD—GILLFILLAN.—On Dec. 13th, at Hampstead, Arthur Beresford Kingsford, M.D., to Esther Mary, sixth daughter of the late Rev. Thos. Gillfillan.

Millington, M.A., and Mrs. Millington, of Bedford.

DEATHS.

CASS.—On Dec. 12th, suddenly, whilst out shooting near Bettws-y-Coed, North Wales, Edward Eden Cass, M.B., B.S., of Goolie, Yorkshire.

COLEY.—On Dec. 13th, at Eldon-square, Newcastle-on-Tyne, Frederic Collins Coley, M.D., J.P., aged 75 years.

PRIESTLEY.—On Dec. 15th, Joseph Priestley, B.A., M.D., D.P.H., late M.O.H., Lambeth.

WHITE.—On Dec. 13th, at Albany-villas, Home, Charles Percival White, M.B. Camb., M.V.O., aged 67.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE HEALTH OF CYPRUS.

THE island of Cyprus, situated in the Eastern Mediterranean, is about 140 miles in greatest length from east to west, and about 40 miles in greatest breadth from north to south. In 1878 the island passed under the administration of Great Britain, and, on the outbreak of war with Turkey in 1911, was annexed to the British Crown. In 1925, Letters Patent giving to Cyprus the status and name of a Colony, and constituting the office of Governor of the Colony in place of that of High Commissioner, were passed under the Great Seal.

According to the official report on the affairs of the island for the year 1927, recently issued through the Colonial Office, the estimated population on Dec. 31st was about 330,500, as against 310,709 shown in the census return taken in 1921. The total number of births registered in the island during the year was 8580, being 25.2 per 1000 of the population. The deaths numbered 5328, equivalent to 15.6 per 1000. The bulk of the inhabitants are of the Orthodox Greek-Christian faith, and belong to the Antiochian Church of Cyprus. Of the remainder, some 65,000, or approximately one-fifth of the population, are Moslems. There is also an Armenian community, which tends steadily to increase, and a distinct though not numerous Latin colony. Except for the endemic prevalence of malarial fever, the climate is healthy and temperate, and with proper precautions there should be no difficulty in enjoying complete immunity from this disease. The heat and humidity in certain localities during the summer months impose a certain strain, but access to the hills is easily practicable within a very short distance. The climate during the winter might almost be described as ideal, combining as it does invigorating cold with clear sunshine. The continued dullness of more northern climes is seldom experienced, and a rainy day is invariably succeeded by a cloudless sky.

Epidemic Disease.

Public health in 1927 was satisfactory. Cyprus remained free from plague, typhus, and other virulent diseases common in the Near East. There was also no case of rabies during the year. The prevailing diseases, other than malaria and phthisis, were those of the digestive and respiratory systems, influenza, and dysentery. In one village there was a serious outbreak of enteric attributed to a contaminated water-supply, but the general incidence of this disease has of recent years been greatly diminished. There was an increase in the number of trachoma cases; but the increase would seem to be apparent rather than actual and due to the opening of special eye dispensaries. Phthisis, according to the official figures, would appear to have been slightly more prevalent than in 1926. Owing, however, to the extreme reluctance of private practitioners to report cases of phthisis, its actual incidence is hard to determine.

Malaria.

Although climatic conditions were more favourable in 1927, 500 more cases of malaria were treated than in the previous year. This may to a great extent be attributed to the opening of fresh dispensaries and to the growing readiness of the people to apply for medical aid. It is interesting to observe that whereas in 1913 out of 30,458 patients 24.1 per cent. had malaria, in 1927 out of 58,456 patients 16.10 per cent. had malaria; and that, whilst in 1913, 21.82 per cent. of 9175 children who were examined had enlarged spleens, in 1927 12,155 children were examined and the spleen-rate was 12.9 per cent. The antimalaria work carried out in 1927 include the cleaning of streams and drains, the draining and reclaiming of marshes, screening or filling in of wells, and the stocking of tanks and wells with fish. House-to-house inspections were made by the sanitary inspectors, large quantities of larvicide were used, and quinine was distributed free of charge to the population. Lectures, accompanied by lantern slides, were given in several places with a view to arousing the intelligent co-operation of the people in antimalaria work.

The infant mortality-rate in Cyprus is unduly high. This is attributed in part to malaria, in part to inherited syphilis, and in part to want of proper care and attention. An infant welfare centre was opened in Nicosia, and a nurse, specially trained in child welfare work, visited the centre twice weekly and gave advice and treatment. At the end of the year a venereal disease clinic was opened in Nicosia, and a specialist appointed.

Hot Spots.

In the autumn of 1927 Dr. A. E. Horn, C.M.G., visited Cyprus in order to report on the working of the medical department. During the year there were two hospitals and a

sanatorium, maintained by the Government, in operation, together with four Government-aided hospitals, 27 rural dispensaries, and seven branch dispensaries. Each rural dispensary is the headquarters of a rural medical officer, who works among the village population. The duties of these officers are sanitary as well as medical, and they are engaged in particular in the campaign against malaria.

The total number of beds in the Government hospitals is 223, and almost 4000 patients were admitted during 1927, 721 surgical operations being performed. At the close of the year 130 inmates were detained at the lunatic asylum, as against 118 at its commencement: 19 persons were discharged as cured, and ten died; the number of new cases admitted was 41. The accommodation of the institution was ample. Lunacy in Cyprus is generally of a mild form, and restraint had to be resorted to in three cases only.

Leprosy.

The number of lepers admitted to the Leper Farm, which is run on the lines of a village, with its own church, mosque, and schools, was five, and the number of lepers detained at the close of the year amounted to 81. There were six deaths, all of which were advanced cases of the disease. Some of the inmates have been treated with gynocardate of soda, leprol, mogrol, and preparations of antimony, with some success. In nodular cases disappearance of the nodules and growth of the eyebrows has been noted. It is satisfactory to record that the disease has recurred in none of the five cases released on parole. The number of children at the end of the year in the home for the healthy children of lepers was nine, all of whom remained free from any sign of the disease.

Meteorology.

At Nicosia the absolute mean temperature for 1927 was 66.5° F.; the mean maximum was 79.2° F., and the mean minimum 55.9° F. Rainfall for the last ten years has averaged 20.33 inches per annum; the mean for 1927 was 16.81 inches, as compared with 28.19 inches for 1926. Twenty-two earthquake shocks were recorded during 1927; they were all felt in Limasol. Two of the shocks were classified as severe, and occasioned a certain amount of damage to buildings. There are numerous resorts in the hills at altitudes varying from 6000 to 2000 feet, such as Mount Troödos or Kantara, where the summer season, lasting from June to the end of September, can be passed in eminently healthy surroundings and without discomfort or inconvenience. On Troödos during the 1927 season the maximum shade temperature was 91° F. and the minimum 48° F.

THE SEASONAL INCIDENCE OF THE PLAGUE.

IN his scholarly little handbook, "The Boar's Head Tavern in Eastcheap,"¹ Dr. Kenneth Rogers gives (p. 49) some interesting figures of the monthly incidence of the last five epidemics of plague. With the help of the Rev. H. J. Fynes-Clinton, who contributes a foreword to the book, he has investigated the old registers of the city parishes of St. Michael, Crooked Lane, and St. Magnus, and has constructed a table of great epidemiological interest. The carrier of the disease, the rat flea, was especially abundant in the summer months, and the mortality as shown by the burial lists, from being negligible in June, showed a sharp rise culminating in September and sinking again almost to nothing in December. The average September figure for the two parishes in the last five plague years was over 72; the figures for the winter months were under four. Another unexpected result is that the final outburst, that of 1665, was by no means the deadliest. The September burials were 69 in that year, but in 1603 they were 89, and in 1563 they were 92. Attention has probably been focused on the "Great Plague" partly because it was the last and partly because of the unique description of it written by Pepys in his diary.

THE CONTINENTAL ANGLO-AMERICAN MEDICAL DIRECTORY.

WE have received from Dr. B. Sherwood-Dunn, hon. secretary and treasurer of the Continental Anglo-American Medical Society, a copy of a revised directory. This list of Anglo-American doctors practising in continental Europe going year by year by Dr. Thomas Linn, who died last July. The list is intended to serve as a bond of union between practitioners, and should help to circumvent the boycott of the English-speaking doctor in the foreign resort by hotel managers and others who naturally prefer to recommend home products. The list will be supplied free of charge to anyone who applies to Dr. Sherwood-Dunn at 51, Boulevard Victor-Hugo, Nice, A.-M., France.

¹ The Historical Association, Ltd., 57, Maiden-lane, Covent Garden, W.C. 1927. Pp. 32. 4s. 6d.

"BAY MOUNT," PAIGNTON.

Dr. Stanford Park's sixth annual report covers the experience of the year 1927 at the home for alcoholism, drug habits, and neurasthenia, of which he is resident medical superintendent. During the year 43 new patients were admitted for treatment; 6 patients remained over from 1926. Of the total number 36 were males and 13 females. There were 23 cases of alcoholism, 4 cases of alcoholism plus marked neurasthenia, 14 drug cases (5 of which also took alcohol to excess), and two cases of neurasthenia without any history of drink or drugs. No case of delirium tremens occurred, but there were two severe cases of alcoholic neuritis, and two of cirrhosis of the liver. The results obtained were good and at times even remarkable. Dr. Park remarks that there is no apparent reason why practically all patients, who are not mentally affected, should not be cured by the treatment provided. There is sometimes the difficulty that patients at the end of three or four weeks' treatment feel so well as to think they are cured, and it may be difficult to persuade them to complete their cure. The unwilling patient remains the most difficult problem. Dr. Park distinguishes three types: (1) the man who denies that he drinks to excess, or that he drinks at all; (2) the man who says he can stop when he likes, and that treatment is unnecessary; (3) the man who frankly says he likes drink and won't give it up. If they are persuaded to submit to treatment they always require much coaxing and exhortation. Nevertheless an apparently hopeless case is sometimes cured. Occupation with work or play is regarded as most important, and patients are urged to occupy their time, while will-power and self-confidence are built up by appropriate methods. Dr. Park concludes his report with a plea to physicians and patients' relations to send cases early. To delay, in the hope that the patient will improve or be cured at home, is mistaken kindness.

APPOINTMENT DIARIES FOR DENTAL SURGEONS.

THE Diary of Appointments for Dental Surgeons has just been issued by the Dental Manufacturing Company at the price of 6s. 6d. or, interleaved with blotting-paper, at 8s. It is a convenient and handy book with appointments for each day at half-hourly intervals. A separate address book is included which slips into a pocket in the cover. We have also received a similar appointment book from Messrs. John Bale, Sons, and Danielsson. This is published at the price of 7s. 6d. or, interleaved with blotting-paper, at 9s. 6d. This also provides for half-hourly appointments and contains information on the times of dentition, motor licences, and the agreed scale of charges for members of approved societies. Another useful feature is a complete list of members of the British Dental Association arranged according to the localities where they practise. Both of these diaries are well suited for their purpose.

THE MODIFICATION OF THE OESTRAL CYCLE IN RATS.

It has been stated (Lyman, *Amer. Jour. Phys.*, 1928, lxxxv., 414) that adrenalectomy brings about the suppression of the oestral cycle in rats. In a series of experiments¹ made by Del Castillo on female rats, the extirpation of the adrenals is shown to have no greater effect upon the oestral cycles of the animals than does a similar operation in which these glands are left intact. None of the animals died as a result of the operation. The onset of puberty, when young rats are adrenalectomised, is not affected. These results are in agreement with those of Zondek (*Klin. Woch.*, 1927, vi., 685) on white mice, and it is probable that Lyman's results are to be attributed to the results of operation—14 out of 17 animals died within a period of 27 days following operation.

In two brief communications which appear in the same journal (pp. 1404, 1405) Del Castillo shows that removal of the spleen and pineal body respectively produces no effect other than that attributed to operative trauma; and he also confirms the observations of Buschke, Zondek, and Berman (*Klin. Woch.*, 1927, vi., 683) that the appearance of oestrus is temporarily inhibited by subcutaneous administration of thallium. Sodium fluoride and irradiation with ultra-violet light produce a similar result; but in these experiments the cycles did not reappear and the rats remained in a condition of permanent diestrus.

THE address of the North Kensington Welfare Centre, on whose annual report we commented last week is 12, Telford-road, Ladbroke-grove, London, W. 10.

Corrigendum.—In Mr. W. H. Ogilvie's article on "A Pneumatic Bone Operating Set" (*THE LANCET*, Dec. 8th, p. 1177), the pressure in the cylinders of compressed air should read 120 atmospheres, not pounds.

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(Continued from p. 1276.)

THE following is the text of the official bulletins which have been issued during the King's illness by Sir Stanley Hewett and Lord Dawson.

THURSDAY, DEC. 13TH. 10.45 A.M.

The King has had some sleep. The local condition is satisfactory. The weakness and toxæmia are considerable, but the pulse is steady and His Majesty is not losing ground. (Signed also by Sir Hugh Rigby.)

8.15 P.M. Though the King is still suffering from exhaustion, there is a slight improvement in His Majesty's condition this evening. The local condition remains satisfactory. (Signed also by Sir Hugh Rigby.)

FRIDAY, DEC. 14TH. 10.30 A.M.

The slight improvement in the King's condition noted last evening is maintained. Any progress must be slow and difficult. (Signed also by Sir Hugh Rigby.)

8.15 P.M. The King has had a somewhat disturbed day, and the general condition is not quite so satisfactory. The pulse, however, remains steady. (Signed also by Sir Hugh Rigby.)

SATURDAY, DEC. 15TH. 11 A.M.

The King has had several hours' sleep. The local condition is so far satisfactory. There is no increase in the exhaustion and the pulse remains steady. (Signed also by Sir Hugh Rigby.)

7.20 P.M. His Majesty has had a quiet day, with some sleep. Though the pulse remains steady and the fever is now moderate, the exhaustion persists. It had been decided to employ ray therapy as part of the treatment. (Signed also by Sir Hugh Rigby, Dr. Robert Stanton Woods, and Dr. Frank Howitt.)

SUNDAY, DEC. 16TH. 11 A.M.

In spite of a restless night His Majesty's general condition has slightly improved. (Signed also by Sir Hugh Rigby.)

8 P.M. The King has had a quiet day and the improvement in His Majesty's condition noted this morning has been maintained. (Signed also by Sir Hugh Rigby.)

MONDAY, DEC. 17TH. 10.45 A.M.

The King has had a fair night with some natural sleep towards morning. The slight improvement in His Majesty's condition noted yesterday continues. (Signed also by Sir Hugh Rigby.)

8.15 P.M. The King has this afternoon been somewhat restless, and the progress recently noted has not been continued during the last few hours. (Signed also by Sir Hugh Rigby.)

TUESDAY, DEC. 18TH. 11 A.M.

In spite of the King having passed a disturbed night there is a slight improvement in both the general and local conditions. (Signed also by Sir Hugh Rigby.)

8.10 P.M. The King has passed a quiet day, and the progress noted this morning has continued. (Signed also by Sir Hugh Rigby.)

WEDNESDAY, DEC. 19TH. 11 A.M.

The King has had a restful night. The slight improvement noted yesterday continues. (Signed also by Sir Hugh Rigby.)

WORK OF THE MIDDLESEX HOSPITAL.—The report for the year 1927 shows that the average weekly cost of each in-patient was £1 10s. 8d., as compared with £5 0s. 1d. for the preceding year. The fall is due mainly to the increased bed occupancy and to the greater number of patients treated owing to the annexe being in use for the whole year. There has again been a heavy increase in out-patients—40,018, against 45,457. The new cases are 41 per cent., and the attendances 50 per cent. greater than in 1922. Attention is directed to the importance of endowing the professional chairs in the University of London attached to the hospital's medical school. Of the seven chairs four are still unendowed.

An Address

ON

PURPURA.

*Delivered before the Monklands Medical Society on
Oct. 23rd*

By WALTER K. HUNTER, M.D., D.Sc. GLASG.,

MURHEAD PROFESSOR OF MEDICINE IN THE UNIVERSITY
OF GLASGOW.

PURPURA may be briefly described as a condition in which there are spontaneous extravasations of blood into the skin or mucous membranes. The purpuric spot, a dark red macule varying in size from 1 to 3 mm. in diameter, is perhaps the most characteristic manifestation of these hemorrhages, and so has given the name to the hemorrhagic tendency. But the hemorrhages may also be pin-point in size (petechiæ), or take the form of larger extravasations, called ecchymoses. Moreover, the bleeding need not be confined to the skin and mucous membranes, for it may be subcutaneous, into the interstitial tissue of the viscera, from serous surfaces, or into the retina or globe of the eye. The amount of blood effused varies greatly in the different cases and in the same case from time to time. Sometimes the effusion consists of blood plasma only, producing urticaria in the cutis, angioneurotic œdema in subcutaneous tissues, or "arthritis" in a joint. Sometimes the urticarial and purpuric eruptions are present at the same time, or one may alternate with the other. The essential fault seems to be in the capillary wall which, for the time being, allows undue transudation of blood or certain of its component parts. Plasma only may be transuded, as in urticaria and the effusion into joints; there may be a diapedesis of red corpuscles, as in the purpuric spot; or there may be effusion of whole blood (plasma and corpuscles) as in the ecchymoses and certain other hemorrhages. In purpura injury to the outer layer of the skin is rare and hence no blood escapes from that surface, but in purpura of mucous surfaces, although in uncomplicated cases there is no ulceration, the blood seems to escape between the cells of the intact mucous membrane, and much may be lost. This escape of blood from mucous membrane is analogous to the escape of serous fluid in hay-fever, asthma, and other vasomotor disturbances.

CLASSIFICATIONS OF PURPURA.

These various manifestations of purpura, occurring by themselves or in various combinations, have naturally produced a dissimilar clinical picture in different cases; hence arose the four types of purpura described in the older text-books. These are:—

(1) *Purpura simplex*, in which the lesion is confined mostly to the skin and consists mainly of purpuric spots which come out in crops on the extensor surfaces of the limbs.

(2) *Purpura rheumatica* (Schönlein's disease), where there is pain and effusion in the joints, in addition to various skin disturbances, such as purpuric spots, urticaria, erythema, or diffuse and nodular, and ecchymoses.

(3) *Hæmorrhagic purpura*, with serous or hemorrhagic effusion into the intestine, giving rise to intestinal colic, vomiting, and diarrhoea.

(4) *Purpura hemorrhagica*, where bleeding from mucous surfaces is the outstanding feature.

Nevertheless, these various appearances are but different symptoms produced by the fault in the capillary wall, and the classification, while it may have been convenient, is at times confusing, for the types tend to overlap each other, and an individual case may have the features of two or more different groups.

More recently an attempt has been made to classify purpura from the point of view of the exander-

tion of the blood. In all cases of purpura there tends to be anemia of the secondary type, and its degree of severity will depend on (a) the amount of blood lost, and (b) the capacity of the blood-forming organs to make good the loss. Along with the deficiency in red cells and hæmoglobin there is frequently a degree of leucocytosis, affecting chiefly the polymorphonuclear leucocytes, although in some cases there is a persistent leucopenia. This variation in the number of leucocytes may again depend on the activity of the bone-marrow, but it may also be influenced by an infective agent, either the causal organism producing the purpura or a secondary infection. The anemia of purpura is therefore in no way distinctive. There are, however, certain features of the blood which are supposed to be more or less characteristic of purpura.

(1) In many cases there is a diminution in the number of platelets from, say, 350,000 to 5000 or less. The platelets, too, may be larger than normal and altered in shape. (2) The bleeding time may be considerably increased. (3) Though coagulation time is normal, the clot when formed does not retract normally. (4) The tourniquet test is positive—i.e., when the arm is constricted for two to five minutes a crop of petechial spots appears distal to the pressure area. These four signs are not met with in all cases of purpura, and it has been maintained that they are positive only in purpura hemorrhagica. More recently, therefore, the purpuras have been divided into two types which are claimed to be essentially different. The first consists of purpura hemorrhagica (sometimes called essential thrombopenic purpura, and also Werlhof's disease), and the second of Schönlein-Henoch purpura (also spoken of as anaphylactoid purpura), which includes simple purpura, purpura rheumatica, and Henoch's purpura. In the former group (Werlhof's disease) there is bleeding from mucous membranes and purpuric spots and ecchymoses on the skin, but none of the other skin manifestations—such as urticaria, œdema, or erythema—and no arthritis. There is also little tendency to bleeding into solid organs, and rarely nephritis. There is, however, thrombopenia, increase in bleeding time, and a clot which does not contract. In the second form (anaphylactoid purpura) the bleeding time, retraction of clot, and number of platelets are normal, and there may be any of the symptoms characteristic of purpura rheumatica and Henoch's purpura. In the former group fever is said never to occur, whereas it is not uncommon in anaphylactoid purpura.

From the descriptive point of view this classification may be more useful than the older one; but I find it difficult to believe that in essential thrombopenia and anaphylactoid purpura we are dealing with two different clinical entities or, indeed, that there is any essential difference between them. In drawing this distinction the chief emphasis has been laid on the presence or absence of thrombopenia. It is true that there is a diminution in the platelet count in most of the more severe cases of purpura hemorrhagica, at least during the active phase of the disease. But the platelet count is also reduced in many of the more severe cases of anaphylactoid purpura, and it has not been satisfactorily demonstrated that thrombopenia always precedes the purpura, or that a platelet rise is a precursor of the arrest of hemorrhage. Indeed, the thrombopenia is perhaps more probably a sequel of the bleeding than its cause, or it may be that the factor (toxin?) which produces the bleeding at the same time determines the thrombopenia. We do not understand the functions of the blood-platelets, much less the significance of their variations in number. They are presumably produced in the bone-marrow, and their number may vary with its activity and vitality. We know that their count may alter with great rapidity within the course of a few hours without any recognisable cause. By the injection of anti-platelet serum they have been caused to disappear from the circulation without ill-effect to the patient and without the appearance of purpura. In hemophilia, when

"BAY MOUNT," PAIGNTON.

Dr. Stanford Park's sixth annual report covers the experience of the year 1927 at the home for alcoholism, drug habits, and neurasthenia, of which he is resident medical superintendent. During the year 43 new patients were admitted for treatment; 6 patients remained over from 1926. Of the total number 36 were males and 13 females. There were 23 cases of alcoholism, 4 cases of alcoholism plus marked neurasthenia, 14 drug cases (5 of which also took alcohol to excess), and two cases of neurasthenia without any history of drink or drugs. No case of delirium tremens occurred, but there were two severe cases of alcoholic neuritis, and two of cirrhosis of the liver. The results obtained were good and at times even remarkable. Dr. Park remarks that there is no apparent reason why practically all patients, who are not mentally affected, should not be cured by the treatment provided. There is sometimes the difficulty that patients at the end of three or four weeks' treatment feel so well as to think they are cured, and it may be difficult to persuade them to complete their cure. The unwilling patient remains the most difficult problem. Dr. Park distinguishes three types: (1) the man who denies that he drinks to excess, or that he drinks at all; (2) the man who says he can stop when he likes, and that treatment is unnecessary; (3) the man who frankly says he likes drink and won't give it up. If they are persuaded to submit to treatment they always require much coaxing and exhortation. Nevertheless an apparently hopeless case is sometimes cured. Occupation with work or play is regarded as most important, and patients are urged to occupy their time, while will-power and self-confidence are built up by appropriate methods. Dr. Park concludes his report with a plea to physicians and patients' relations to send cases early. To delay, in the hope that the patient will improve or be cured at home, is mistaken kindness.

APPOINTMENT DIARIES FOR DENTAL SURGEONS.

THE Diary of Appointments for Dental Surgeons has just been issued by the Dental Manufacturing Company at the price of 6s. 6d. or, interleaved with blotting-paper, at 8s. It is a convenient and handy book with appointments for each day at half-hourly intervals. A separate address book is included which slips into a pocket in the cover. We have also received a similar appointment book from Messrs. John Bale, Sons, and Danielsson. This is published at the price of 7s. 6d. or, interleaved with blotting-paper, at 9s. 6d. This also provides for half-hourly appointments and contains information on the times of dentition, motor licences, and the agreed scale of charges for members of approved societies. Another useful feature is a complete list of members of the British Dental Association arranged according to the localities where they practise. Both of these diaries are well suited for their purpose.

THE MODIFICATION OF THE OESTRAL CYCLE IN RATS.

It has been stated (Lyman, *Amer. Jour. Phys.*, 1928, lxxxv., 414) that adrenalectomy brings about the suppression of the oestral cycle in rats. In a series of experiments¹ made by Del Castillo on female rats, the extirpation of the adrenals is shown to have no greater effect upon the oestral cycles of the animals than does a similar operation in which these glands are left intact. None of the animals died as a result of the operation. The onset of puberty, when young rats are adrenalectomised, is not affected. These results are in agreement with those of Zondek (*Klin. Woch.*, 1927, vi., 685) on white mice, and it is probable that Lyman's results are to be attributed to the results of operation—14 out of 17 animals died within a period of 27 days following operation.

In two brief communications which appear in the same journal (pp. 1404, 1405) Del Castillo shows that removal of the spleen and pineal body respectively produces no effect other than that attributed to operative trauma; and he also confirms the observations of Buschke, Zondek, and Berman (*Klin. Woch.*, 1927, vi., 683) that the appearance of oestrus is temporarily inhibited by subcutaneous administration of thallium. Sodium fluoride and irradiation with ultra-violet light produce a similar result; but in these experiments the cycles did not reappear and the rats remained in a condition of permanent diestrus.

THE address of the North Kensington Welfare Centre, on whose annual report we commented last week is 12, Telford-road, Ladbroke-grove, London, W. 10.

Corrigendum.—In Mr. W. H. Ogilvie's article on "A Pneumatic Bone Operating Set" (*THE LANCET*, Dec. 8th, p. 1177), the pressure in the cylinders of compressed air should read 120 atmospheres, not pounds.

THE KING'S ILLNESS.

OFFICIAL BULLETINS.

(Continued from p. 1276.)

THE following is the text of the official bulletins which have been issued during the King's illness by Sir Stanley Hewett and Lord Dawson.

THURSDAY, DEC. 13TH. 10.45 A.M.

The King has had some sleep. The local condition is satisfactory. The weakness and toxæmia are considerable, but the pulse is steady and His Majesty is not losing ground. (Signed also by Sir Hugh Rigby.)

8.15 P.M. Though the King is still suffering from exhaustion, there is a slight improvement in His Majesty's condition this evening. The local condition remains satisfactory. (Signed also by Sir Hugh Rigby.)

FRIDAY, DEC. 14TH. 10.30 A.M.

The slight improvement in the King's condition noted last evening is maintained. Any progress must be slow and difficult. (Signed also by Sir Hugh Rigby.)

8.15 P.M. The King has had a somewhat disturbed day, and the general condition is not quite so satisfactory. The pulse, however, remains steady. (Signed also by Sir Hugh Rigby.)

SATURDAY, DEC. 15TH. 11 A.M.

The King has had several hours' sleep. The local condition is so far satisfactory. There is no increase in the exhaustion and the pulse remains steady. (Signed also by Sir Hugh Rigby.)

7.20 P.M. His Majesty has had a quiet day, with some sleep. Though the pulse remains steady and the fever is now moderate, the exhaustion persists. It had been decided to employ ray therapy as part of the treatment. (Signed also by Sir Hugh Rigby, Dr. Robert Stanton Woods, and Dr. Frank Howitt.)

SUNDAY, DEC. 16TH. 11 A.M.

In spite of a restless night His Majesty's general condition has slightly improved. (Signed also by Sir Hugh Rigby.)

8 P.M. The King has had a quiet day and the improvement in His Majesty's condition noted this morning has been maintained. (Signed also by Sir Hugh Rigby.)

MONDAY, DEC. 17TH. 10.45 A.M.

The King has had a fair night with some natural sleep towards morning. The slight improvement in His Majesty's condition noted yesterday continues. (Signed also by Sir Hugh Rigby.)

8.15 P.M. The King has this afternoon been somewhat restless, and the progress recently noted has not been continued during the last few hours. (Signed also by Sir Hugh Rigby.)

TUESDAY, DEC. 18TH. 11 A.M.

In spite of the King having passed a disturbed night there is a slight improvement in both the general and local conditions. (Signed also by Sir Hugh Rigby.)

8.10 P.M. The King has passed a quiet day, and the progress noted this morning has continued. (Signed also by Sir Hugh Rigby.)

WEDNESDAY, DEC. 19TH. 11 A.M.

The King has had a restful night. The slight improvement noted yesterday continues. (Signed also by Sir Hugh Rigby.)

WORK OF THE MIDDLESEX HOSPITAL.—The report for the year 1927 shows that the average weekly cost of each in-patient was £4 16s. 8d., as compared with £5 0s. 1d. for the preceding year. The fall is due mainly to the increased bed occupancy and to the greater number of patients treated owing to the annexe being in use for the whole year. There has again been a heavy increase in out-patients—19,018, against 45,457. The new cases are 41 per cent., and the attendances 50 per cent. greater than in 1922. Attention is directed to the importance of endowing the professional chairs in the University of London attached to the hospital's medical school. Of the seven chairs four are still unendowed.

An Address

ON

PURPURA.

Delivered before the Monklands Medical Society on
Oct. 23rd

By WALTER K. HUNTER, M.D., D.Sc. GLASG.,

MURHEAD PROFESSOR OF MEDICINE IN THE UNIVERSITY
OF GLASGOW.

PURPURA may be briefly described as a condition in which there are spontaneous extravasations of blood into the skin or mucous membranes. The purpuric spot, a dark red macule varying in size from 1 to 3 mm. in diameter, is perhaps the most characteristic manifestation of these hæmorrhages, and so has given the name to the hæmorrhagic tendency. But the hæmorrhages may also be pin-point in size (petechiæ), or take the form of larger extravasations, called ecchymoses. Moreover, the bleeding need not be confined to the skin and mucous membranes, for it may be subcutaneous, into the interstitial tissue of the viscera, from serous surfaces, or into the retina or globe of the eye. The amount of blood effused varies greatly in the different cases and in the same case from time to time. Sometimes the effusion consists of blood plasma only, producing urticaria in the cutis, angioneurotic œdema in subcutaneous tissues, or "arthritis" in a joint. Sometimes the urticarial and purpuric eruptions are present at the same time, or one may alternate with the other. The essential fault seems to be in the capillary wall which, for the time being, allows undue transudation of blood or certain of its component parts. Plasma only may be transuded, as in urticaria and the effusion into joints; there may be a diapedesis of red corpuscles, as in the purpuric spot; or there may be effusion of whole blood (plasma and corpuscles) as in the ecchymoses and certain other hæmorrhages. In purpura injury to the outer layer of the skin is rare and hence no blood escapes from that surface, but in purpura of mucous surfaces, although in uncomplicated cases there is no ulceration, the blood seems to escape between the cells of the intact mucous membrane, and much may be lost. This escape of blood from mucous membrane is analogous to the escape of serous fluid in hay-fever, asthma, and other vasomotor disturbances.

CLASSIFICATIONS OF PURPURA.

These various manifestations of purpura, occurring by themselves or in various combinations, have naturally produced a dissimilar clinical picture in different cases; hence arose the four types of purpura described in the older text-books. These are:—

(1) *Purpura simplex*, in which the lesion is confined mostly to the skin and consists mainly of purpuric spots which come out in crops on the extensor surfaces of the limbs.

(2) *Purpura rheumatica* (Schönlein's disease), where there is pain and effusion in the joints, in addition to various vasomotor disturbances, such as purpuric spots, urticaria, erythema (both diffuse and nodular), and ecchymoses.

(3) *Henoch's purpura*, with serous or hæmorrhagic effusion into the intestine, giving rise to intestinal colic, vomiting, and diarrhoea.

(4) *Purpura hæmorrhagica*, where bleeding from mucous surfaces is the outstanding feature.

Nevertheless, these various appearances are but different symptoms produced by the fault in the capillary wall, and the classification, while it may have been convenient, is at times confusing, for the symptoms tend to overlap each other, and an individual case may have the features of two or more different types.

Recently an attempt has been made to classify purpura from the point of view of the examination

tion of the blood. In all cases of purpura there tends to be anæmia of the secondary type, and its degree of severity will depend on (a) the amount of blood lost, and (b) the capacity of the blood-forming organs to make good the loss. Along with the deficiency in red cells and hæmoglobin there is frequently a degree of leucocytosis, affecting chiefly the polymorphonuclear leucocytes, although in some cases there is a persistent leucopenia. This variation in the number of leucocytes may again depend on the activity of the bone-marrow, but it may also be influenced by an infective agent, either the causal organism producing the purpura or a secondary infection. The anæmia of purpura is therefore in no way distinctive. There are, however, certain features of the blood which are supposed to be more or less characteristic of purpura. (1) In many cases there is a diminution in the number of platelets from, say, 350,000 to 5000 or less. The platelets, too, may be larger than normal and altered in shape. (2) The bleeding time may be considerably increased. (3) Though coagulation time is normal, the clot when formed does not retract normally. (4) The tourniquet test is positive—i.e., when the arm is constricted for two to five minutes a crop of petechial spots appears distal to the pressure area. These four signs are not met with in all cases of purpura, and it has been maintained that they are positive only in purpura hæmorrhagica. More recently, therefore, the purpuras have been divided into two types which are claimed to be essentially different. The first consists of purpura hæmorrhagica (sometimes called essential thrombopenic purpura, and also Werlhof's disease), and the second of Schönlein-Henoch purpura (also spoken of as anaphylactoid purpura), which includes simple purpura, purpura rheumatica, and Henoch's purpura. In the former group (Werlhof's disease) there is bleeding from mucous membranes and purpuric spots and ecchymoses on the skin, but none of the other skin manifestations—such as urticaria, œdema, or erythema—and no arthritis. There is also little tendency to bleeding into solid organs, and rarely nephritis. There is, however, thrombopenia, increase in bleeding time, and a clot which does not contract. In the second form (anaphylactoid purpura) the bleeding time, retraction of clot, and number of platelets are normal, and there may be any of the symptoms characteristic of purpura rheumatica and Henoch's purpura. In the former group fever is said never to occur, whereas it is not uncommon in anaphylactoid purpura.

From the descriptive point of view this classification may be more useful than the older one; but I find it difficult to believe that in essential thrombopenia and anaphylactoid purpura we are dealing with two different clinical entities or, indeed, that there is any essential difference between them. In drawing this distinction the chief emphasis has been laid on the presence or absence of thrombopenia. It is true that there is a diminution in the platelet count in most of the more severe cases of purpura hæmorrhagica, at least during the active phase of the disease. But the platelet count is also reduced in many of the more severe cases of anaphylactoid purpura, and it has not been satisfactorily demonstrated that thrombopenia always precedes the purpura, or that a platelet rise is a precursor of the arrest of hæmorrhage. Indeed, the thrombopenia is perhaps more probably a sequel of the bleeding than its cause, or it may be that the factor (toxin?) which produces the bleeding at the same time determines the thrombopenia. We do not understand the functions of the blood-platelets, much less the significance of their variations in number. They are presumably produced in the bone-marrow, and their number may vary with its activity and virility. We know that their count may alter with great rapidity within the course of a few hours without any recognisable cause. By the injection of anti-platelet serum they have been caused to disappear from the circulation without ill-effect to the patient and without the appearance of purpura. In hæmophilia, when

spontaneous hæmorrhage is the outstanding symptom, there is no thrombopenia.

The increase of the bleeding time, which is also said to be characteristic of purpura hæmorrhagica, is no doubt met with in certain cases of purpura where bleeding has been going on, and in most cases it varies directly with the thrombopenia. It seems, however, to vary with the activity of the disease, as well as at different parts of the body when tested at the same time. It is therefore somewhat inconsistent, even in purpura hæmorrhagica. Before we admit the significance of thrombopenia and bleeding time we must know more about them, not only in the different types of purpura, but also during different phases of the illness in individual cases. The same applies to retraction of the clot and the tourniquet test (which, by the way, may produce urticaria rather than petechiæ).

SYMPTOMATOLOGY.

Purpura tends to be intermittent, each attack lasting from one or two days to five or six weeks, with intervals of variable duration when the patient seems in good health. It may also take a chronic form, fresh manifestations of the disease appearing every few days; this may go on for years. On the other hand, it may be very acute, with one or two attacks within a short period and great effusion of blood, ending fatally in the course of a few hours to one or two weeks. In contrast to this is *simple purpura*, a mild disturbance with purpuric spots coming out in crops over a period of three to six weeks, and often with no recurrence. The bleeding from mucous membranes most often takes the form of an epistaxis, and then, in order of frequency, comes bleeding from gums, urinary tract, uterus, stomach, and intestine. Hæmoptysis is rare. There may be bleeding from only one mucous surface, or several may be involved at the same time; recurrences may affect the same mucous membrane each time, although not invariably.

Before an attack there is frequently some slight constitutional disturbance, such as headache, malaise, nausea, vomiting, pains in the limbs, and sometimes slight fever. These symptoms vary considerably in different cases. The blood pressure is usually low in purpura.

Most cases ultimately recover (the mortality has been put down at 15 per cent.), but the more chronic cases may suffer a great deal of debility and ill-health. Certain complications may supervene, such as nephritis, endocarditis, cerebral hæmorrhage and, in Henoch's type of the disease, ulceration of the stomach or intestine. The nephritis may be acute, with dropsy, or it may be chronic, and it seems to be most often met with in the Schönlein-Henoch type of purpura. The intracranial hæmorrhage is usually meningeal in origin, and may be subpial, subdural, or pachymeningitic. Endocarditis seems to be most common in purpura with arthritis. Piney¹ suggests that endocarditis lenta is nearly related to purpura, and maintains that the skin manifestations and hæmaturia in the former are not embolic, but have a similar origin to those symptoms in purpura.

DIAGNOSIS.

The purpuric rash is very distinctive and will at once suggest the disease, but in its absence it is easy to miss the significance of the arthritis of Schönlein's type, the abdominal symptoms of Henoch's type, or hæmorrhage from a single mucous surface. The arthritis of purpura has often been mistaken for, and treated as, "rheumatism," and the abdominal colic may closely simulate embolism or thrombosis of the mesenteric artery, or some other form of the "acute abdomen." When there is bleeding from one mucous membrane only, the difficulty of diagnosis may be very real. Kidd² has recently recorded 24 cases of hæmaturia where he has been able to

demonstrate by cystoscopic or direct examination numerous petechiæ on the mucous surface of the bladder or in the pelvis of the kidney. Some of these patients had purpuric spots on the skin, some had arthritis, and some bleeding from another mucous membrane. In such cases the nature of the hæmaturia is less difficult to appreciate, but in the absence of those other signs of purpura, or with an associated nephritis, as there was in one of his cases, the cause of the blood in the urine may remain obscure, at least without the aid of the cystoscope. The rather profuse and continuous hæmaturia which is sometimes met with in chronic nephritis, especially in children, is possibly sometimes purpuric, and a number of cases with too profuse bleeding at the menstrual periods are without doubt cases of purpura. Possibly so-called gastrostaxis has a similar explanation. Purpura is not likely to be mistaken for hæmophilia, for the history of the two conditions is very different; but less severe cases of scurvy, especially if the gums are not affected, may have a rash very like that of purpura. In scurvy, however, the purpuric spots are usually confined to the hair follicles, and situated on the outer aspects of the legs and thighs. This gives a characteristic rough surface, which is felt on passing the hand over the eruption, and which is not present in purpura.

PATHOGENESIS.

The chief lesion in purpura is an undue permeability, for the time being, of the capillary wall, which permits the transudation of red corpuscles, plasma, or whole blood. The questions are: What causes this state of the capillary? and how does it cause it? We know that certain manifestations of purpura can be produced experimentally, and in some people much more easily than in others. In so-called secondary purpura the purpura macula can be induced by injecting cobra venom. It sometimes follows the administration of such drugs as quinine and iodide of potassium. It may also occur in cerebro-spinal fever, small-pox, or scarlet fever, and it is the characteristic rash of typhus fever. The urticarial rash, too, can be induced by a variety of irritants, such as the bite of certain insects, the sting of the nettle, and even mechanical irritation, as in dermatography. It is a symptom in serum disease. Indeed, urticaria is one of the commonest appearances in the allergic state, and the existence of an undue sensitisation or allergy in the urticarial subject seems to have been established. It might therefore be argued that in certain cases of purpura this undue sensitisation of the capillary wall determines an abnormal reaction to specific agents, and that whether it is inherited or acquired it constitutes the *predisposing* factor in the disease. In other diseases there are "bad antitoxin formers," and it may be that in purpura we have what has been called an immunological defect.

Of the exciting cause we have little definite information but, as in asthma, it is probably different in different cases, and perhaps different in the same case at different times. There may be some fault in the digestive tract allowing foreign proteins in an unaltered state to enter the blood stream. Or the cause may be a physical agent, such as trauma, light, or heat, which, acting on a hypersensitive tissue, liberates a histamine-like body. Kidd has drawn attention to the frequency of a local focus of infection in his series, and he isolated from some of his cases a streptococcus in pure culture. Sometimes sore-throat was complained of before the onset of purpura; sometimes it was tonsillectomy or the extraction of septic teeth that preceded the attack. He suggests that in these patients the purpura was due to a streptococcal infection of throat, teeth, or perhaps bowel, producing possibly a mild toxæmia rather than a septicæmia.

It seems to be taken for granted by certain writers that the deficiency of platelets is the cause of the bleeding. They say that with a platelet count above 35,000 or 40,000 bleeding becomes completely arrested and that purpura cannot be produced experimentally

¹ Recent Advances in Hematology, 1927, p. 175.

² Kidd: Proc. Roy. Soc. Med., 1928, vol. xxi., No. 6.

unless there is a lower figure. With this I cannot agree. I have had under my care patients with a much higher count in whom bleeding was active, and other cases with a lower count and no signs of the disease. At the present time it seems more judicious to view the platelet count in much the same way as we do the leucocyte count. Leucopenia may be a symptom of disease but not its cause, and the same may apply to thrombopenia in purpura.

TREATMENT.

In the absence of any proper understanding of the ætiology of purpura, treatment must be more or less empirical. It is reasonable, however, to treat all septic foci, such as septic teeth and tonsils. Drugs seem to have little real effect on the disease, although calcium salts are usually prescribed with the idea that they lessen transudation through the vessel wall. Horse serum is known to check bleeding in many cases, and it is given in 25 c.cm. doses every alternate day for three doses in all. In recurring cases the same dose may be given three times a week every two or three months. This serum has most often been given in the form of antistreptococcal serum, and it seems to be as efficient when administered by the mouth as subcutaneously. If given subcutaneously, subsequent doses may produce serum disease. Kidd has tried an autogenous streptococcus vaccine but without much benefit, and when the dose was too large it produced an attack of purpura. If this treatment fails and the patient is unduly anæmic a blood transfusion should be given. Its effect may be only temporary, but it will probably stop the bleeding and lessen the anæmia.

In chronic cases, where other treatment has failed, splenectomy must be considered. The results, if the patient survives the operation, have been most encouraging, for there is often immediate arrest of the bleeding and sometimes what seems to be a complete cure. Why excision of the spleen should remove the tendency to hæmorrhage is not clear, but it seems now to be a fairly well-established fact. There is usually an immediate rise in the platelet count after the operation, but this high count does not persist and yet the tendency to hæmorrhage has disappeared; as we have seen, there is no satisfactory proof that the platelet is a causal factor in the bleeding tendency. Platelets are derived from the bone-marrow, and their increase or diminution in number must be determined by the activity of production in the marrow and the facility with which they pass into the blood stream. It may be that excision of the spleen activates this process, as it seems to arrest the hæmorrhage, but of that we have no certain knowledge. Formerly it was stated that only the cases of essential thrombopenic purpura (purpura hæmorrhagica) benefited by splenectomy. That, however, seems to need confirmation. It is naturally the cases with excessive bleeding which specially call for more drastic treatment, but in the other types of purpura there seems no good reason to withhold splenectomy if other treatment has failed. Splenectomy in the more severe cases of purpura is a serious operation with a fairly high mortality, and other means of treatment should therefore first be considered. Rest in bed seems an important part of the treatment, and in milder cases it often checks the bleeding without other measures.

CASE RECORDS.

I have notes of 30 patients with purpura, and of these I have grouped 8 as purpura simplex, 11 as purpura hæmorrhagica, 10 as of the Henoch-Schönlein type, and one as a possible purpura fulminans. This division is no doubt somewhat arbitrary, as in certain cases of purpura simplex and Henoch's purpura the bleeding from mucous membranes was almost as considerable as that in less severe cases of purpura hæmorrhagica. Indeed, at times it is difficult to say into which category a particular case should go. Also, I have not found it possible to classify my cases according to their platelet count, which seems

to me so inconstant as to be of little use to the clinician; in any case the figures at my disposal are inadequate.

The first case is one of Henoch's purpura which was operated on as an "acute abdomen," and it is of special interest in that the appearances of the intestine were noted during life as well as at the post-mortem examination some three weeks later.

CASE 1, male, aged 50, was under observation in hospital from May 26th to the time of his death on June 8th, 1914. The illness started on April 4th with pains in the knee-, ankle-, and elbow-joints, which were diagnosed and treated as rheumatic. He was confined to bed for five weeks. After that he felt so well that he went to a convalescent home, where he was able to walk half a mile at a time. On the sixth day, however, he complained of severe pain in the abdomen, accompanied by vomiting, and the vomitus contained brownish matter like coffee-grounds. With the onset of the abdominal symptoms there was a return of the arthritis, and now for the first time a purpuric eruption appeared. The spots were confined to the hands and feet, but there they were very abundant. During the next ten days he had a great deal of abdominal pain, coming on in paroxysms, and sometimes lasting for hours at a time. It was always worse when the bowels moved. There was frequent diarrhoea and vomiting, and the vomitus contained altered blood. The abdominal symptoms were so severe as to suggest to the patient's doctor a ruptured gastric ulcer, and with this diagnosis he was sent into the surgical wards of the Royal Infirmary, under Prof. Peter Paterson.

On admission the patient was very collapsed and bathed in a cold sweat. The abdominal pain was almost continuous. The temperature was 100° F., and the pulse-rate 80 and of poor quality. There was marked rigidity and tenderness on palpation of the abdomen, especially in the epigastric and hypochondriac regions. The urine contained a trace of albumin. The patient was explored the next day (May 16th) by Prof. Paterson, who reported as follows: "When the abdomen was opened 5 oz. of clear straw-coloured fluid escaped. About half the small intestine was congested, the appearance suggesting an early stage of peritonitis. Over the congested area were numerous dark-coloured patches, apparently due to extravasated blood and situated just under the peritoneal covering. These varied in size from that of a pin-point to half an inch in diameter. The intestinal walls were distinctly thickened, and the lumen was distended, but not markedly so. Scattered over the affected part of the intestine at irregular intervals were distinct constrictions, such as might be produced by localised spasm of the muscle coats. These constrictions involved the whole circumference of the intestine and measured about half an inch in breadth. The walls of these parts did not seem as thick as those immediately adjoining, and they were not so congested. The pelvis contained intestine which appeared normal."

After the operation the pain in the abdomen was better, but there were still cramp-like pains from time to time which were sometimes very severe. There was melæna for several days, and on May 18th pain in the elbows, wrists, and finger-joints; these joints were swollen, as were also, although to a lesser extent, the knee- and ankle-joints. On the 20th fresh purpuric spots appeared over the affected joints, especially on their extensor aspects. There was still no hæmaturia, but the albumin had increased in amount.

Ten days after the operation the patient was transferred to the medical wards, when it was elicited that in former years he had had several attacks of "rheumatism," in one of which purpuric spots had appeared on his skin. There was no history of any renal disease or gastric trouble. The teeth were carious and some were absent. The heart and lungs seemed normal, and there was no enlargement of liver or spleen. The systolic blood pressure registered 130 mm. of mercury. The urine had a specific gravity of 1022, and contained abundant albumin but no blood or sugar. There was a faint trace of bile. There were numerous epithelial and granular casts and a few pus cells. The purpuric spots varied in size from that of a pin-head to half an inch in diameter, and were situated mostly over the extensor surfaces of the joints. The red cells numbered 3,260,000, and the white cells 9100; the hæmoglobin was 43 per cent. The films showed little abnormality beyond some variation in the size of the red cells. There were no nucleated red cells. The platelets were not counted but, judging from the films, they seemed neither increased nor decreased in number. Of the white cells 75 per cent. were polymorphonuclear, 10 per cent. lymphocytes, 2 per cent. monocytes, and 1 per cent. marrow cells. The coagulation time was not increased, but the blood did not contract as in normal blood. The patient lived for about a fortnight after he had been to the medical wards, but during that time

spontaneous hæmorrhage is the outstanding symptom, there is no thrombopenia.

The increase of the bleeding time, which is also said to be characteristic of purpura hæmorrhagica, is no doubt met with in certain cases of purpura where bleeding has been going on, and in most cases it varies directly with the thrombopenia. It seems, however, to vary with the activity of the disease, as well as at different parts of the body when tested at the same time. It is therefore somewhat inconstant, even in purpura hæmorrhagica. Before we admit the significance of thrombopenia and bleeding time we must know more about them, not only in the different types of purpura, but also during different phases of the illness in individual cases. The same applies to retraction of the clot and the tourniquet test (which, by the way, may produce urticaria rather than petechiæ).

SYMPTOMATOLOGY.

Purpura tends to be intermittent, each attack lasting from one or two days to five or six weeks, with intervals of variable duration when the patient seems in good health. It may also take a chronic form, fresh manifestations of the disease appearing every few days; this may go on for years. On the other hand, it may be very acute, with one or two attacks within a short period and great effusion of blood, ending fatally in the course of a few hours to one or two weeks. In contrast to this is *simple purpura*, a mild disturbance with purpuric spots coming out in crops over a period of three to six weeks, and often with no recurrence. The bleeding from mucous membranes most often takes the form of an epistaxis, and then, in order of frequency, comes bleeding from gums, urinary tract, uterus, stomach, and intestine. Hæmoptysis is rare. There may be bleeding from only one mucous surface, or several may be involved at the same time; recurrences may affect the same mucous membrane each time, although not invariably.

Before an attack there is frequently some slight constitutional disturbance, such as headache, malaise, nausea, vomiting, pains in the limbs, and sometimes slight fever. These symptoms vary considerably in different cases. The blood pressure is usually low in purpura.

Most cases ultimately recover (the mortality has been put down at 15 per cent.), but the more chronic cases may suffer a great deal of debility and ill-health. Certain complications may supervene, such as nephritis, endocarditis, cerebral hæmorrhage and, in Henoch's type of the disease, ulceration of the stomach or intestine. The nephritis may be acute, with dropsy, or it may be chronic, and it seems to be most often met with in the Schönlein-Henoch type of purpura. The intracranial hæmorrhage is usually meningeal in origin, and may be subpial, subdural, or pachymeningitic. Endocarditis seems to be most common in purpura with arthritis. Piney¹ suggests that endocarditis lenta is nearly related to purpura, and maintains that the skin manifestations and hæmaturia in the former are not embolic, but have a similar origin to those symptoms in purpura.

DIAGNOSIS.

The purpuric rash is very distinctive and will at once suggest the disease, but in its absence it is easy to miss the significance of the arthritis of Schönlein's type, the abdominal symptoms of Henoch's type, or hæmorrhage from a single mucous surface. The arthritis of purpura has often been mistaken for, and treated as, "rheumatism," and the abdominal colic may closely simulate embolism or thrombosis of the mesenteric artery, or some other form of the "acute abdomen." When there is bleeding from one mucous membrane only, the difficulty of diagnosis may be very real. Kidd² has recently recorded 21 cases of hæmaturia where he has been able to

demonstrate by cystoscopic or direct examination numerous petechiæ on the mucous surface of the bladder or in the pelvis of the kidney. Some of these patients had purpuric spots on the skin, some had arthritis, and some bleeding from another mucous membrane. In such cases the nature of the hæmaturia is less difficult to appreciate, but in the absence of those other signs of purpura, or with an associated nephritis, as there was in one of his cases, the cause of the blood in the urine may remain obscure, at least without the aid of the cystoscope. properly, whereas on March 19th the serum was seen to have extruded from the clot in one and a half hours.

She reported two and a half years later and seemed to be in excellent health. The first menstrual period after the operation was rather excessive, lasting for about ten days, but after that the monthly loss was normal.

CASE 4, female, aged 17, was admitted to hospital on April 6th, 1924. For the past seven years she had bruised very readily. In 1919 she had had a severe bleeding from the nose which lasted, off and on, for three days, and left her very weak. She was in bed at this time for four months. For six months before admission the menstrual periods had been regular, but each lasted a fortnight. She had had swelling and pain of her ankle-joints 12 months before admission, but no other sign of arthritis. She had not worked for five months owing to weakness. There was no history of bleeding in other members of her family.

Heart, lungs, and abdominal organs showed no abnormality. The spleen was not enlarged, and there was no albumin or blood in the urine. The pelvic organs seemed normal. The teeth were in good order except for two molars in the left upper jaw. She was in hospital for four months, and the outstanding feature of her illness was the amount of blood lost at her periods. The blood count, which was made once a week, would show a rise to nearly normal just before the period, followed by a loss of two or three million cells at the end of the period. The red corpuscles ranged in this way from 5,230,000 to 1,430,000 per c.mm., the white cells from 9000 to 4000, and the hemoglobin from 80 per cent. to 25 per cent. Of the white cells 67 per cent. were polymorphonuclear, 31 per cent. lymphocytes, and 2 per cent. eosinophils. The blood platelets numbered 201,000 per c.mm. when the period had been going on for three days. The only other bleedings during her stay in hospital were a very severe epistaxis on May 20th, estimated at about 20 oz., and an abundant purpuric rash, extending from the knees to the ankles, which appeared on April 28th at the onset of a menstrual period.

Treatment was by calcium in various forms, iron, and horse serum. Improvement was slow, but ultimately the patient got quite well and remained so for about 18 months, during which time the menstrual periods were regular and lasted about seven days. In the autumn of 1926 she had an attack of what was thought to be influenza. After this she was up and about, though not feeling quite well, when suddenly her period set in and seems to have continued for a fortnight, at the end of which time she died, presumably from loss of blood.

The fifth case illustrates the association of purpura with a septic focus in the jaw.

CASE 5, a man, aged 38, was admitted to hospital on June 7th, 1916, with the history that three weeks before, when drunk, he had received a blow on the jaw. Two days later he had noticed that there was slight but continuous bleeding from the gums, which were swollen and discoloured. The bleeding continued at intervals for a week, and a few days later increased in severity. For about ten days there had been purpuric spots on trunk, neck, arms, and legs. He remained at work until June 4th, when he felt so sick and giddy that he was obliged to go to bed. There had been no pains in the joints, and—except for slight epistaxis—no bleeding from other mucous surfaces. He had contracted syphilis three years before, but there had been no lesions in the mouth and no previous hemorrhages. His diet seems to have been that of the ordinary labourer. His mouth was foul and his breath offensive; his teeth were few and bad. The gums were swollen, with blood extravasated under the mucous membrane, and there was constant oozing of blood from both upper and lower jaws. There was also a purulent discharge from the lower jaw on the left side. There were purpuric spots all over the body and bruises on the arms and one ankle. There was no oedema and no albumin in the urine. Heart, lungs, and abdominal organs showed no abnormality, and the Wassermann reaction was negative. There were no nucleated red cells, and the blood picture was that of a secondary anaemia, with leucopenia affecting the polymorphonuclear cells (the polymorphonuclear cells were 14 per cent. and the lymphocytes 84 per cent.). The platelets were not counted, but there were few visible in the films, suggesting a definite thrombopenia. The patient was treated by horse serum, calcium lactate, and adrenalin chloride, but he grew steadily worse and died 13 days after admission.

At the autopsy for a confirmation a septic focus was found in the root of one of the left lower molars. The gums were inflamed and showed a suppuration, with superficial abscesses extending forward to the canine teeth. There were abscesses in the heart and liver, and a pneumonic consolidation of the left upper lobe. There were a few purpuric spots on the abdominal wall. The histological examination of the jaw examination, but histologically the

granular leucocytes seemed much diminished in number. The spleen was large, pale, and soft.

Case 6 seems to be a case of purpura simplex, and I quote it because the platelet count was so variable and at one time showed an increasing thrombopenia with the general improvement of the patient.

CASE 6, a boy of 10, was first admitted to hospital on Nov. 12th, 1925. Two years before he had had an epistaxis after a blow on the nose. Since then the nose had bled about every three weeks, the flow lasting for about two hours at a time. There had been no bleeding from other mucous surfaces, no arthritis, and no abdominal symptoms. He had, however, always bruised rather easily. Purpuric spots on the skin were first noted at the end of June, 1925, and since then he had hardly ever been without them. They appeared in crops, and often one crop appeared before the previous one had faded. Each crop lasted about three weeks. Previous illnesses were unimportant. A maternal grandmother had bruised too readily and a grandfather had suffered from asthma, but there was no history of bleeding in the other members of the family.

On examination the face looked rather puffy, but the urine was normal. There were purpuric spots scattered over the trunk, arms, and legs. They varied in size from $\frac{1}{16}$ to $\frac{1}{4}$ inch in diameter. There were also half a dozen bruises from $\frac{1}{4}$ to 1 inch in diameter. The teeth were carious and the tonsils enlarged. The examination of the heart, lungs, and abdominal organs was negative.

In the four weeks during which the patient was under observation the purpuric spots gradually faded and no fresh ones appeared. The red cells varied from 3,830,000 to 4,780,000 per c.mm.; the white cells from 12,187 to 21,562; hemoglobin from 70 per cent. to 75 per cent.; and platelets from 100,000 to 264,000. Of the white cells 46 per cent. were polymorphonuclears, 34 per cent. lymphocytes, 13 per cent. monocytes, 4 per cent. transitionals, 2 per cent. eosinophils, and 1 per cent. mast cells.

The patient was readmitted to hospital on Sept. 13th, 1928, with a purpuric rash all over the body, most abundant just below the crest of the ilium. There were also three or four bruises on the skin. During the preceding three years he had almost never been free from purpuric spots, fresh crops continuously coming out. He had had one or two bleedings from the nose, the last nine months before. The liver and spleen were not enlarged, and there was no albumin in the urine. The day after admission there was some slight bleeding from the gums, but no fresh purpuric spots in the three weeks after admission. He was treated by rest in bed and three doses of horse serum at intervals of 48 hours. In three weeks' time the red cells had gradually increased in number from 4,500,000 to 6,230,000, and the hemoglobin from 70 per cent. to 93 per cent. The white cells ranged from 13,680 to 6230.

The platelets count showed a definite thrombopenia, the platelets seeming to lessen as the red cells increased in number. It was as follows: Sept. 13th, 13,680 per c.mm.; 18th, 27,360 per c.mm.; 21st, 11,480 per c.mm.; 26th, 6230 per c.mm. On admission the bleeding time from the left ear was seven minutes; from the right ear 25 minutes. Coagulation time was normal. The tourniquet test was positive.

The last case is possibly purpura fulminans, but death might have been due to the hemorrhage into the suprarenals.

CASE 7, a girl, aged 1 year, was admitted to hospital on Feb. 18th, 1910, at 2 A.M., and died two hours later. She had been quite well until the night before—i.e., the 17th—when she had had an attack of diarrhoea about 9 P.M. The motions were dark in colour. The baby cried and tossed about, and was apparently very ill. The lips became blue, and an eruption came out and spread quickly all over the body. On admission the temperature was 101° F., and the respiration-rate 84. The purpuric eruption was universal, even on the scalp. The spots varied in tint from bright red to blue-black, and in size from a pinpoint to a five-shilling piece. The lips were cyanosed. There was a history that the mother of the child had readily.

At the post-mortem examination the axillary and mesenteric glands were slightly enlarged, and the Peyer's patches and solitary follicles were prominent. The thymus was enlarged and weighed 14 oz. The spleen weighed 11 oz. and presented a number of dark areas suggestive of hemorrhage. There were small patches of hemorrhage into the lungs, and hemorrhages into both suprarenal capsules, so that there was almost no normal suprarenal tissue left. In the kidneys there was congestion of the vessels around the periphery of the pyramids and the urine was red in colour. The liver was not examined.

I wish to acknowledge my indebtedness to Dr. W. Mackay, my University assistant, who is responsible for the blood platelet counts.

he was clearly not well. He was lethargic and took little interest in what was going on round about him. On June 6th he had a slight rigor, with the appearance of collapse, followed by paroxysms of acute abdominal pain. There was marked rigidity and tenderness of the abdomen, but no fever or increase of pulse-rate and no melæna. On the 7th there was again much abdominal pain, and the urine contained blood and numerous blood-casts. On the 8th he suddenly collapsed, could not speak, became comatose, and died an hour later.

At the *post-mortem examination* the whole small intestine was found intensely congested, suggesting an infarction, but there was no sign of embolism or thrombosis. There were numerous ulcers in the small intestine, and the whole mucosa was unhealthy and showed signs of digestion. The walls of the intestine were thickened, but there was none of the constrictions seen at the operation. There was an ulcer on the anterior wall of the stomach which had perforated, but was walled off by adhesions. On the interior of the stomach there were several small ulcers and much ecchymosis. There was a localised peritonitis on the left side of the diaphragm and a small amount of yellow-coloured fluid was present. The kidneys showed signs of parenchymatous nephritis. Suprarenals, liver, spleen, heart, and lungs presented no abnormality. The brain was very oedematous but there were no hæmorrhages. The pathologist adds: "The result of the examination suggested that the condition was due to some disturbance of the vasomotor apparatus."

The second case is an example of the Henoch-Schönlein group, running a rather chronic course and complicated by nephritis and acute endocarditis.

CASE 2, a married woman, aged 52, was first admitted to hospital on May 22nd, 1921. For five or six years she had had "rheumatic" pains in her joints from time to time. In June, 1920, hard tender swellings appeared on the back and inner sides of the thighs. The skin was red over the swollen areas, and later it took on a purple or bruised appearance. In time the swellings disappeared, leaving only the discoloured skin. At the end of June the ankles became swollen and painful, and some months later the knees were similarly affected. In February, 1921, the calf of the leg became tender, swollen, and inflamed, and this was diagnosed as "phlebitis." At the end of March the left knee was more swollen and later the skin over it discoloured. Smaller swellings (urticaria?) with subsequent discoloration appeared later on the back of the right hand and upper arm, and again on the thighs. For a year there had been intermittent bleeding from the right nostril. The family history was unimportant, and the social conditions were good. The patient, however, had for some years past had a good deal of nursing to do, and she thought she was run down.

On admission to hospital there was bruising of both thighs and of the extensor surface of the left leg. The right calf felt indurated, was tender, and had a bruised appearance. There was ecchymosis of the lower abdomen and swelling of the dorsum of the right hand. Both ankles were swollen and tender, and the left knee was swollen with effusion and the skin over it was bruised. This joint was punctured and blood, which proved to be sterile, was withdrawn. The gums were edentulous and seemed healthy. Heart, lungs, and abdominal organs presented no abnormality. The systolic blood pressure was 130 mm. of mercury. The urine contained no albumin. The red cells numbered 3,150,000, the white cells 7600, and the hæmoglobin was 52 per cent. Examination of films showed little abnormality. Of the white cells 56 per cent. were polymorphonuclear, 34 per cent. lymphocytes, and 10 per cent. monocytes and transitionals. The coagulation time was 15 minutes. The patient was in hospital for a month and was dismissed, still with swelling of the joints and a certain number of ecchymoses. During the month she had a good deal of pain in the stomach and flatulence.

She was readmitted four years later—i.e., on May 11th, 1925. She had never been free of pain in the joints since leaving hospital, but the severity varied from time to time and she was obliged to rest a great deal in bed. She had likewise many recurrences of the ecchymosis, which came out, as it were, in crops. There had been no recurrence of bleeding from the nose and no bleeding from bladder, bowel, or lungs. She had lost her appetite, suffered from nausea, and generally was in very poor health. On the inner surface of the right leg there was a large ecchymosis, extending from the knee to the ankle. The leg felt indurated and was painful to the touch. The knee- and ankle-joints were swollen and the normal contour of the joints was lost, but there was no fluctuation. The appearances of the left leg were like those of the right, but not so pronounced. There were also ecchymoses on the back of the hands and purpuric spots over the abdomen. The blood pressure was now 110/70 mm. of mercury, and there was a faint trace of albumin in the urine. The red cells ranged from $3\frac{1}{2}$ to $2\frac{1}{2}$ millions,

and the white cells numbered 6250. The hæmoglobin varied from 36 per cent. to 28 per cent. Of the white cells 70 per cent. were polymorphonuclear and 30 per cent. lymphocytes. The platelets were not enumerated, but judging from the numbers in the films it seemed that there could be no considerable thrombopenia. The coagulation time was 3 minutes. During the 13 days the patient was under observation she had two attacks of very severe abdominal pain, each lasting for about 24 hours. During this time, too, urticaria appeared on the trunk, followed by purpuric spots, some of which were situated on the raised skin of the urticaria nodule. After this she gradually went down hill and died on May 24th, 1925.

At the *post-mortem examination* an acute recent endocarditis of the mitral valve was found, clusters of vegetations being present on the auricular side of the cusps. There was no sign of chronic valvular disease. The lungs were oedematous, and there were a number of small subpleural hæmorrhages over both lungs. The liver was pale and showed cloudy swelling; hæmosiderine reaction was negative. The spleen was enlarged and typically septic, but films showed no organisms. The kidneys were both smaller than normal. The cortex was narrow and the appearances were those of chronic interstitial nephritis. There were submucous hæmorrhages in the stomach but none in the intestine. The brain and its membranes were oedematous, and there was an effusion of blood-stained serum over the left cerebral hemisphere and below the dura. The right knee-joint contained blood-clot. There were also many subcutaneous and intramuscular hæmorrhages, and microscopic areas of hæmorrhage into both kidney and liver.

The third and fourth cases I regarded as purpura hæmorrhagica, but in neither was there a considerable thrombopenia. Case 3 shows the good result of splenectomy; in Case 4 the spleen was not excised.

CASE 3, female, aged 27, was admitted to hospital on Jan. 21st, 1926. The illness had started about ten weeks before with a feeling of weariness and weakness, and on one or two occasions she had fainted. On Nov. 11th purpuric spots began to appear on the skin, first on the left thigh, then round the right knee, with one large patch behind this knee, then six spots on the dorsum of the right foot, varying in size from a sixpence to a florin, and a large patch extending from calf to heel on the outer aspect of the leg. There were a few spots on the left foot and five or six round the left knee. All these spots were level with the surface of the skin, and they were fading before spots came out on the arms, a month later. On the arms the spots were raised above the surface, like blue blisters. There was one of these on the right elbow and three round the left elbow. Three days later petechial spots appeared on the shoulders and neck, and later still on the abdomen. A week after the onset of the skin eruption bleeding started from the nose, and later from the gums. The epistaxis was at times rather profuse, and occurred each morning for a week. Then the menstrual periods became excessive, lasting sometimes for about a fortnight; the loss of blood was very considerable, especially towards the beginning of the period.

The patient had had diphtheria and scarlet fever in childhood, but otherwise had been very healthy. There was no history of "rheumatism," and no previous history of a hæmorrhagic tendency. The upper teeth were artificial and the lower in good condition. The breath was foul. There was no enlargement of liver or spleen, and heart and lungs were normal. For five weeks after admission bleeding from some mucous membrane was going on almost continuously; not more than three to four days elapsed without some hæmorrhage, which was chiefly from the nose but also from the uterus, where at times it was very considerable. There was also some bleeding from the gums and, from time to time, hæmaturia, but there were never any tube-casts in the urine. A fresh crop of purpuric spots appeared on the thorax, back and front, on Feb. 9th. Treatment with large doses of calcium lactate and later with "fibrogen," first by the mouth and then subcutaneously, had little effect. The subcutaneous injections produced a local reaction which was painful, and the swelling did not subside for some days.

The spleen was excised by Prof. Paterson on March 1st, and the patient made a satisfactory recovery. A week after the operation an urticaria appeared, with albuminuria, but these cleared up within a few days. The red cells ranged from 2,880,000 per c.mm. on admission to 1,580,000 on Feb. 20th. The range of white cells was from 4657 to 7810, and hæmoglobin from 60 per cent. to 30 per cent. After the operation the red cells rose to 4,450,000 and the hæmoglobin to 85 per cent. The highest leucocyte count after the operation was 13,750. Before the operation the blood platelets ranged from 112,500 to 359,375. The bleeding time before operation was ten minutes, and after operation five minutes. Before the operation the clot did not contract

base. In 10 per cent. of the cases there was well-marked gallop rhythm at the apex and, although the interpretation of this sign is still under consideration, the general consensus of opinion strongly testifies to its serious significance. Several other types of arrhythmia (premature contractions, &c.) were observed and a large number of the cases had some variety of murmur, the most usual being a systolic murmur at the mitral area with partial or complete replacement of the first heart sound.

The blood pressure figures show wide variations as may be seen in the following summary:—

	Per cent.
(1) Systolic blood pressures of or exceeding 160 mm. Hg	30
(2) Systolic blood pressures of or less than 120 mm. Hg	18
(3) Systolic blood pressures intermediate between 120 and 160 mm. Hg	52

Moreover, eight of the cases included under (1) showed readings of 200 or over, the maximum being 240, which persisted in a patient aged 68 during periods of relative physical comfort and the ultimate stages of decompensation. The following conclusions appear to have practical value:—

(a) Myocardial degeneration is not necessarily associated with low blood pressure.

(b) Myocardial degeneration and supertension frequently coexist.

(c) Variations in the level of the blood pressure may be expected in the decompensation stages of myocardial degeneration, high tension cases exhibiting a temporary rise in blood pressure, low tension cases a further decline.

(d) Return of compensation following high pressure failure in myocardial degeneration may be associated with a fall in the level of the blood pressure.

(e) Progressive narrowing of the pulse pressure range is a sign of grave significance, particularly if, as frequently occurs in myocardial degeneration with hypertension, the diastolic figure is abnormally high.

Finally may be mentioned that group of phenomena peculiar to stasis in the venous side of the circulatory system, for some degree of stagnation is inevitable when the mechanical efficiency of the ventricular musculature is prejudiced by degenerative changes in its structure. These signs vary in intensity with the degree of myocardial incompetence. In the earlier stages the process of stagnation will be confined to the proximal venous channels (the venæ cavae and pulmonary veins), but sooner or later the peripheral circuit is bound to become involved and then significant signs begin to appear. These include a varied group of phenomena: cyanosis, engorgement of the superficial veins (especially obvious in the large venous trunks at the base of the neck), pulmonary congestion, enlargement of the liver, serous effusions, dropsy, &c., which bear witness to the surcharged venous circuit and the raised pressure it is called upon to sustain in conditions of myocardial incompetence and secondary dilatation.

Diagnosis.

The diagnosis of myocardial degeneration depends upon a well-balanced inquiry into the subjective complaints of the patient, combined with the objective evidence of clinical and instrumental examination. The patient, more often than not past middle life, will have experienced symptoms typical of progressive impairment of exercise-response (effort syndrome), and frequently the history is characteristic of anginal complications. In the majority of cases there will be definite clinical evidence of cardiac enlargement and the value of a careful radiological examination cannot be overestimated, for often obesity will render palpation and percussion valueless. Changes in the quality of the heart sounds may be noted in all cases of myocardial degeneration, weakening of their intensity being the rule in the more frankly typical cases of fatty degeneration, while accentuation and prolongation will be more usual in cases combining myocardial degeneration with high blood pressure. Variations of pulse pressure may be found, premature beats, and arrhythmias such as those of the type of the "heart block," &c., being especially

common, but it should be clearly recognised that irregularity of rhythm is by no means essential to the diagnosis of myocardial degeneration. In the same way murmurs, apart from indicating the additional presence of valvular discrepancy, reveal nothing of the actual efficiency of the myocardial structure.

As a rule there is some significant change in the pulse; the rate may be abnormally slow in senile patients or when there is definite heart-block, but on the other hand a fast pulse is extremely common in cases of myocardial degeneration, and this may become exaggerated as the circulatory compensation diminishes. The pulse tension is often raised, and there may be well-marked evidence of a generalised vascular sclerosis with varying degrees of impairment of renal efficiency. Irregularities in the rhythm are exceedingly frequent and their differential diagnosis needs careful investigation. The more usual forms of arrhythmia in myocardial degeneration include:—

1. Pulse intermissions secondary to premature contractions or some form of heart-block.
2. The gross arrhythmia typical of auricular fibrillation.
3. The pulsus bigeminus and other comparable forms of pulse in which there is a definite tendency to grouping of the heart beats.
4. The pulsus alternans.

Certain of these irregularities may be recognised on ordinary physical examination, but some form of graphic tracing, either an electrocardiogram or a polygram, is essential for others.

Another side of the problem is that myocardial degeneration may be an entirely latent process, its course of development being so gradual and insidious that the patient may for a long time overlook the somewhat intangible symptoms of his complaint. It frequently happens in this type of case that moderately acute heart failure develops in a patient hitherto regarded as healthy. Two examples may be quoted:—

1. A male, aged 53, whose previous health had been uniformly good, experienced an acute attack of angina on his return from a day's shooting in the autumn of 1927. After the attack he complained of persistent breathlessness, exhaustion, and fainting sensations, which continued in spite of treatment; also of frequent suggestions of the original pressure-pain on slight effort of any kind or sudden excitement. The clinical findings four weeks after the initial attack were briefly as follows:—

Heart considerably enlarged downwards and to the left; feeble and diffuse apex impulse in the fifth and sixth space five inches from the mid-line; rhythm regular; first heart sound toneless, distant, and at times definitely split at the apex region; soft systolic murmur at the apex and base; pulse 88, regular, small volume, easily compressed; blood pressure 110 mm. systolic, 88 mm. diastolic; definite cyanosis of the lips and slight oedema of the ankles; electrocardiogram typical of right bundle branch block.

The patient gradually improved during the next two months, but in the third week of his convalescence he died in a severe attack of angina induced by the sudden exertion of moving a heavy chair.

The second case is a somewhat striking example of myocardial degeneration in which no suspicion of heart disorder had been entertained, the previous dominant symptoms being suggestive of gastro-intestinal disturbance.

A male, aged 64, complained of attacks of dull, aching pain in the epigastrium and sensations of strained status, which he was inclined to think entirely dependent on errors of digestion. It was, however, significant that the discomfort invariably coincided with active exertion of any kind taken soon after a meal and, in the more severe attacks, there had recently been a tendency to cramp-like sensations and numbness in both arms. The heart was markedly enlarged to the right and to the left, the apex of dullness extending 2 in. to the right of the mid-line in the fourth space and 4 in. to the left in the fifth space. The rhythm was regular, the first heart sound being replaced by a long flowing systolic murmur at the apex, faintly at the base and at the heart base. The blood pressure was 140 mm. systolic and 100 mm. diastolic, and there was regular stasis in the pulmonary circulation. The electrocardiogram showed T waves inverted in leads I and II, flattened in leads III and aVF, and a prolonged Q wave in lead III. The S wave in all the leads was notched and the T waves were small.

MYOCARDIAL DEGENERATION.*

BY BASIL PARSONS-SMITH, M.D.,
M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR
DISEASES OF THE HEART.

MYOCARDIAL degeneration is an exceedingly common affection and has a somewhat variable symptom-complex, with the phases and features of which it is essential to be thoroughly familiar. As its name implies, the essential factor is degenerative change in the heart muscle, and, since tissue degeneration is invariably associated with reduced functional efficiency, depression of myocardial function will be the inevitable outcome of the degenerative process. The latter may be a primary degenerative deterioration depending upon occlusive lesions in the coronary vessels or it may be secondary to some form of acute or chronic infection of the myocardium. The pathological findings in the cases of primary degeneration include necrosis, fatty change, and fibrosis in the muscle-fibres, together with grosser manifestations such as infarcts, aneurysms, fibrous bands, calcareous patches, &c. While similar changes may be recognised where degeneration follows an inflammatory process, the microscopical findings clearly define the additional presence of myocarditis, and, as often as not, endocarditis, valvulitis, or pericarditis provide coexisting naked-eye evidence of an infectious process.

I have recently analysed the records of 50 cases in whom the outstanding clinical features were typical, and from the salient facts of these records I hope to establish a clear conception of the condition, its outlook, and the prospective limitations of its treatment.

Symptoms.

Symptoms are moderately easy to interpret if we appreciate certain fundamental principles—viz., that degeneration induces impairment of reserve and inefficiency of function, and that cardiac inefficiency will not only limit the range of the heart's response, but will also prejudice the circulation in certain organs, which will themselves manifest symptoms of incompetence.

In the early stages of myocardial degeneration the signs and symptoms are usually vague and inconsistent, for so great is the reserve power of the heart in the healthy that the minor grades of impairment of function do not as a general rule exhibit well-defined subjective or objective peculiarities. On the other hand, careful inquiry will often elicit important facts in the past history; the patient may have noticed certain vague sensations—slight præcordial discomfort, a tendency to breathlessness, palpitation, momentary attacks of giddiness—associated with the ordinary efforts of his daily routine, games, exercise, &c., which he had previously undertaken with impunity. In actual fact, however, the initial manifestations of myocardial degeneration often escape observation entirely, for, in the words of the late James Mackenzie, "the patient rarely presents himself before the physician until the exhaustion of the reserve force has produced some distressing symptom; it may be breathlessness, cardiac asthma, angina pectoris, or bronchitis."

The group of cases whose investigation forms the basis of the present paper included 50 adults of ages between 37 and 75, the average age being 60; the outstanding symptoms were:—

	Per cent.
Breathlessness	80
Anginal phenomena	44
Giddiness, fainting sensations, and syncopal attacks ..	10
Cough	20
Nocturnal wheezing (so-called cardiac asthma) ..	8
Somnolence and deficient mentality ..	4

These illustrate the widespread effects brought about by myocardial degeneration in its fully

* Being an address delivered before the Margate Medical Society.

developed form, and show that the large majority of cases are likely to suffer from breathlessness or the anginal syndrome.

Physical Signs.

Although much valuable information can be gleaned from a careful inquiry into the history, a diagnosis of myocardial degeneration often depends chiefly upon the results of physical examination. For this reason it is essential to recognise that particular complex of physical signs which characterises inefficiency of function on the part of a heart musculature in the process of degeneration. The scope and variability of these physical signs can best be appreciated by the analysis of a group of typical cases. The pulse findings included a wide range of abnormalities. The rate was definitely inconstant; in 70 per cent. of the cases it was raised to 100 or over, in 8 per cent. it was reduced to 40 or under by auriculo-ventricular heart-block, and in the remaining 22 per cent. it was within normal limits. In the large majority the pulse-tension was raised, but in 22 per cent. the pulse was soft and easily compressed. Irregularities of rhythm were present in a large proportion of the cases, their order of frequency being: (1) premature contractions, (2) the gross irregularity typical of auricular fibrillation, and (3) that of heart-block. In addition six of the patients were found to have pulsus alternans, a sign which must always be regarded as extremely serious. Although it is likely to escape recognition by digital examination it is always revealed by a routine blood pressure estimation or a polygraphic tracing.

The after-history of the above six patients is as follows: two were obviously in extremis and died within a fortnight, one cannot be traced, two died within 12 months, one died 15 months after the condition was first recognised. The last combined several features of interest; his case was briefly as follows:—

Male, aged 61, had been under treatment for high blood pressure for ten years; his symptoms included an increasing degree of breathlessness with effort, giddiness when stooping, a gripping pain under the breast bone which, as a rule, spread across the chest and down the left arm, and a tendency to swelling of the ankles at the end of the day. His heart was considerably enlarged downwards and to the left; the impulse was forcible and diffuse in the sixth space, 4½ in. from the mid-line. The rhythm was irregular with frequent premature contractions. There was a loud, blowing, systolic murmur at the apex, replacing the first sound, and an accentuated second sound at the aortic region. The pulse-rate was 92 with well-marked alternation. The vessels were thickened and the blood pressure was 181 mm. systolic, 104 mm. diastolic. There was definite venous engorgement of the jugular vessels, lungs, and mucous membranes, and slight oedema of the ankles. The urine showed a cloud of albumin. The electrocardiographic curves were marked by widening and notching of the R S complexes and complete flattening of the T waves in all the leads.

Under treatment this patient maintained slight improvement for a time, but later his signs and symptoms became progressively aggravated; the anginal syndrome became more intense in spite of complete rest, and the patient was seldom free from what he described as "a bracelet on his arm" and persistent tenderness of the muscles of his chest. He eventually died of an acute coronary thrombosis.

The Heart.

Cardiac enlargement is obvious on physical examination in the large proportion of cases. In 36 per cent. of the group under consideration enlargement was of considerable; in 32 per cent. it was moderate; in 20 per cent. it was slight, and in the remaining 12 per cent. the size did not exceed normal limits. The apex impulse was in no way characteristic—every type of abnormality was encountered—except that the majority of cases had excessive and forcible pulsation, in conformity with the varying degrees of cardiac enlargement. Auscultation revealed certain phenomena, which we regard as definitely helpful in the diagnosis; frequently there was diminution in the tone and intensity of the heart sounds, and in many cases the combination of a poor quality first sound with a relatively accentuated second sound. The first sound was at times inaudible, both at apex and

arterio-sclerosis or of the anigral syndrome. Under these circumstances mental and physical relaxation (possibly a period of complete rest) will be essential; dietary regulations must be laid down, specially emphasising the necessity for small meals, simple, easily digestible food, slow eating, careful mastication, moderation in stimulants, and quietude after meals. Efficient elimination must be ensured by aperients when necessary, with an occasional (once or twice weekly) dose of calomel or blue pill. Adequately restful nights must be secured, such simple remedies as the bromides, luminal, chloralamide, or sulphonal sufficing in certain cases, while others require chloral or opiates. Suitable drug treatment will be needed for well-marked anigral manifestations. Apart from the usual emergency remedies (nitrites, diffusible stimulants, morphia, &c.) certain of these cases seem to respond best to sodium iodide in large and increasing dosage (grs. x.-xl. t.d.s.), others to theominal (luminal in combination with theobromine). Taken over long periods the latter remedies may have depressing effects, to obviate which it is wise to alternate occasional courses (perhaps one week in four) of some reliable general tonic, such as Fowler's solution, combined with strychnine or nux vomica and perhaps an iron preparation.

Digitalis in myocardial degeneration needs most careful consideration; its range of utility is exceedingly narrow for, quite apart from the fact that it may be distinctly contra-indicated, as in partial heart-block, there is no clinical evidence to warrant its routine prescription. Digitalis treatment, except under certain special circumstances, has no useful application in the treatment of myocardial degeneration. The special circumstances include certain of the well-known complications—viz., auricular fibrillation, auricular flutter, and dilatation with congestive heart failure. In the two former digitalis will usually prove an exceedingly efficient remedy and in the latter its effect may be no less dramatic. Improved cardiac action accompanying diuresis and the disappearance of dropsical effusions. Apart from the diuresis, which is probably itself responsible for an improved vital capacity, the effects of digitalis may be singularly negative in cases with normal heart rhythm, and it is especially important to realise that the slowing effect of the drug is, under such circumstances, not forthcoming.

In certain cases it may become necessary to prescribe others of the more reliable diuretics—for instance, diuretin, theocine sodium acetate, urea, salines, &c., and, failing these, novasural injections.

In all cases of congestive heart failure adequate elimination (purgation, diuresis, and skin action) forms a most essential part of the treatment. In the presence of venous stasis depletive treatment—the application of leeches or a venesection—may enormously help the patient's comfort and general progress.

Varying degrees of obesity may complicate the clinical picture and outlook, and suitable treatment must be provided for this condition. Dietary regulations will prescribe simple food, small dry meals, strict moderation in all forms of starchy food, sugars, and fatty nutritious food in normal average quantity; preferably no alcoholic drinks; fluids to be taken between the meals. The question of exercise will require careful consideration; in the relatively mild type of case some form of exercise suitable to the patient's age, build, mentality, financial status, &c., must be chosen. It may be advisable to recommend enforced walking exercise, Swedish exercises, riding, croquet, fishing, games such as croquet or golf, easy dancing, and the like, always instructing the patient to take reasonable precautions against overstrain, and to allow any effort syndrome at the time and only at that time. In the more advanced cases exercise will be of little essential, but restrictions will be much required. General measures, including a moderate to passive movement, walking exercise, and light passive, mild respiratory exercises, and Swedish movements that promote definite

improvement in the metabolism and circulation, and so restore the level of myocardial reserve.

Should there be any suspicion of endocrine unbalance it may be an advantage to prescribe courses of thyroid and pituitary extracts, their effect being closely watched and if possible controlled by testing the basal metabolism at intervals during the treatment.

In a certain proportion of the less advanced cases the question of suitable spa treatment may be entertained, more especially if obesity coexists. The treatment will need to be carefully supervised and excessively strenuous remedial measures should be avoided. In an ordinary case of average severity the scheme of treatment may include dietary regulations, graduated exercise (walking, mild gymnastics, &c.), diuresis and adequate purgation, intestinal lavage, warm baths, mental relaxation, and properly apportioned physical rest. After such a course of spa treatment it may be advisable for the patient to spend a few weeks at some mildly bracing seaside place before returning to his normal routine of life at home.

BACILLUS ABORTUS INFECTION IN MAN.

BY THEODORE THOMPSON, M.D. CAMB.,
F.R.C.P. LOND., F.R.C.S. ENG.

PHYSICIAN TO THE LONDON HOSPITAL.

A SURVEY of the literature proves that very few cases of *Bacillus abortus* infection in man have been reported in this country. A similar infection in cattle, however, has been frequently noted, and in recent years epidemiological evidence has been produced which substantiates the view that the presence of *B. abortus* in cow's milk is the probable cause of human undulant fever occurring sporadically in this country.

It was recognised early in the nineteenth century that abortion occurring in cattle was due to an infection, and abortion was artificially produced by the introduction of vaginal discharge and foetal membranes from infected cases into the vaginas of healthy cows. In 1896 Bang¹ demonstrated the specific cause to be the bacterium now known as the *B. abortus* of Bang. Having cultivated the organism, he was able to bring about abortion by injection of pure cultures into the vagina of pregnant cows and ewes. Injection of cultures into the circulation produced similar results. He also found that the bacillus required for primary cultures, not only a specific medium consisting of nutrient agar to which liquid gelatin and sterile blood serum had been added, but also an optimum growth temperature of 37° C. and a special oxygen content indicated by the fact that the colonies developed in a definite stratum a few millimetres below the surface.

In 1887 Bruce² discovered the *Micrococcus melitensis* in cultures prepared from the spleen in a fatal case of Malta fever.

An extensive investigation was made by a British Commission³ on Mediterranean fever in 1906. The investigators reported that the disease was propagated by goats. They were unable to cultivate *M. melitensis* from the milk of 10 per cent. of the goats supplying milk to various parts of Malta, and from serum reactions they concluded that 41 per cent. of the goats on that island were infected. They were also able to infect monkeys and goats by feeding with cultures isolated from the milk or by feeding with the infected milk itself.

Moller and Eichhorn, as the result of their investigations, concluded that the most important symptom observed in goats affected with Malta fever was the frequency of abortions resulting in the course of the disease. Schneider and Gatten⁴ in 1911 found that the result of an epidemic among goats with each milk that 14 per cent. of the samples tested were infected with *B. abortus*. In 1911 Kennedy⁵ found that contamination of *M. melitensis* was produced by heat dilutions of both milk and serum of certain cases in Iceland.

Bassett-Smith,⁷ following his investigation of 69 samples of cow's milk, pointed out that the milk in some cases had a natural tendency to agglutinate *M. melitensis*, but that if care was taken most of these non-specific reactions could be avoided. He urged that the reaction should always be controlled by other methods of diagnosis before the animal could be considered to be infected. When the samples of milk had been boiled all reactions became negative. Fleischner and Meyer,⁸ in 1917, inoculated guinea-pigs with samples of Certified milk and concluded that *Bacterium abortus* was, for all practical purposes, always present in the Certified milk produced in the San Francisco Bay regions. Evans,⁹ in America, found great difficulty in distinguishing *Bacterium melitensis* from *Bacterium abortus*. She stated that they were alike morphologically, and there was no difference in their biochemical reactions. Both organisms produced the same results when inoculated into pregnant guinea-pigs, and serologically they were closely

patient's blood serum was found to agglutinate both *M. melitensis* and *B. abortus* antigens at a titre of 1:2000. The blood culture and the culture from the urine proved to be sterile. The source of the infection in this case was thought to be goat's milk as the patient had on two occasions taken raw goat's milk. Carpenter and Merriam¹⁶ reported in 1926 two cases of undulant fever; from these they isolated two strains of micro-organisms indistinguishable from *B. abortus*. The cultures behaved like *B. abortus* Bang. Intravenous injections of the cultures produced abortion in two heifers in their first pregnancies, and the cultures were recovered from the placentas and various organs of the fetuses.

From the examination of 488 separate milk samples Wilson and Nutt¹⁷ calculated that about 5.7 per cent. of single milks and 8.8 per cent. of mixed milks were infected with *B. abortus*.

Huddleson,¹⁸ in America, reported three cases of *B. abortus* infection occurring in three graduate

Chart to show the course of the three months undulant fever, the occurrence of rigors, and the effect of vaccine therapy.

related. Considering the close relationship between the two organisms and the reported frequency of virulent strains of *B. abortus* in cow's milk, she expressed surprise that a disease resembling Malta fever did not prevail in America. In 1918 Byam¹⁰ reported a case of Malta fever occurring in England. The patient's blood serum agglutinated *M. melitensis* in dilutions up to 1 in 500.

Meyer and Shaw¹¹ in 1920, from a comparative study of 21 cultures of so-called *M. melitensis* obtained from various sections of the world, and of 32 cultures of *B. abortus* Bang isolated in America and England, concluded that the causative organism of undulant fever in man and of Malta fever in goats cannot be distinguished morphologically or biochemically from the organism responsible for infectious abortion in domesticated animals, and further, that since the so-called *M. melitensis* appears in young cultures as a short rod it should be regarded as *Bacterium melitensis*. Bevan¹² was possible for human females to contract infectious abortion from the ingestion of the organism in milk and dairy products from infected cows. Orpen,¹³ writing in 1923, concluded that the organism of Rhodesian undulant fever was identical culturally, morphologically, and serologically with *B. abortus*, but differed from European *M. melitensis*; they were, however, members of one genus and produced an identical disease in man. Duncan,¹⁴ as the result of investigations conducted in a case of undulant fever contracted in Southern Rhodesia, stated that although experimental proof that *B. abortus* from Rhodesian cattle disease was pathogenic for man had not been supplied, yet the weight of evidence pointed to *B. abortus* as the cause of Rhodesian undulant fever, and to the cow as the source of infection.

In 1925 Box and Bamforth¹⁵ reported another case of undulant fever contracted in this country. The

students engaged in laboratory work. Two of them had worked with cultures of *B. abortus* and the others had handled cultures of *M. melitensis* as well as *B. abortus*. As the result of his investigation, Huddleson concluded that the infection was of bovine origin in two instances, but that *M. melitensis* from the culture may have been responsible for the manifestation of a mild form of the disease in the third case. In 1927 Huddleson,¹⁸ studying the effect of intravenous injections of acriflavine on the *B. abortus* flora of cow's milk, found that the injections were not potent as a therapeutic measure.

Bassett-Smith,²⁰ writing last year on the relationship of undulant fever of man to epidemic abortion of animals, did not favour the theory that *B. abortus* and *B. melitensis* were the same organism with its virulence altered by passage through different animals.

Bamforth,²¹ in 1927, reported two cases of undulant fever occurring in this country. In both instances the blood serum agglutinated *M. melitensis* in a titre of 1:1000, and *B. abortus* 1:2000. Both patients drank cow's milk obtained from farms in their immediate vicinity, and in both instances there was a vague history of abortion occurring amongst the cattle. In neither case was there any history of goat's milk being taken nor were there any goats in the surrounding neighbourhood. Manson-Bahr²² has recorded two more cases in this country where fever of the undulant type was present. The blood serum from the first case was found to agglutinate *M. melitensis* in 1:800 dilution and *B. abortus* 1:1200, whilst the blood serum in the second case agglutinated *M. melitensis* 1:640, *B. abortus* 1:160, and *B. typhosus* 1:320; further investigation proved this case to be a typhoid carrier and the *B. typhosus* was isolated from the faeces. In both instances the blood and urine cultures were sterile.

Sensenich and Giordano²³ in America have recently reported seven cases of *B. abortus* infection in man. Habs²⁴ refers to five cases of undulant fever in man in Germany attributed to infection by *B. abortus*. All occurred in veterinary surgeons in contact with cows suffering from epidemic abortion.

The Author's Case.

History.—The patient was a male, aged 33, a gentleman farmer and a native of Cumberland. He had served with the British Expeditionary Force in France during the war. In 1920 he contracted malaria during a visit to Bombay. Two years later when he returned to England and remained healthy. He had a present illness on June 1st, 1928, when he complained of feeling seedy and had a shivering attack. On June 2nd he motored 300 miles to attend a regimental dinner in London. He was not well during the following week, but did not seek medical advice. On June 10th he returned by motor to Cumberland. The following week he felt feverish.

On June 13th the patient had three rigors; malaria was diagnosed and quinine administered by the mouth. Examination of the blood on June 16th revealed no malarial parasites. The blood culture was sterile. Widal and Wassermann reactions were both negative.

A blood count showed erythrocytes, 5,400,000 per c.mm.; haemoglobin, 80 per cent.; colour-index, 0.7. There was no evidence of basophilic stippling. Leucocytes, 7200 per c.mm. Differential white cell count showed polymuclear leucocytes, 50 per cent.; lymphocytes (mainly large), 46 per cent.; eosinophils, 2 per cent., and basophils, 2 per cent. From June 14th to 21st there had been no shivering attacks and the patient's general condition remained good, although pyrexia was still present (see chart). On June 22nd, 23rd, and 24th he had three more rigors, and daily intramuscular injection of quinine, grs. 10, was given in addition to administration of quinine (grs. 40) by mouth. On June 26th a blood count showed erythrocytes, 5,100,000 per c.mm.; haemoglobin, 75 per cent.; leucocytes, 6000 per c.mm.; polymuclear leucocytes, 57 per cent.; lymphocytes (mainly large), 41 per cent.; basophils, 1 per cent.; eosinophils, 1 per cent. There was no basophilic stippling present and no malarial parasites were seen.

I first saw the patient on June 30th. Routine physical examination revealed no abnormal signs. There was no enlargement of the liver or spleen, no evidence of orchitis, and no enlargement of the lymphatic glands. The patient was removed to a nursing home for further investigation, the results of which will now be recorded.

A blood count showed erythrocytes, 4,400,000 per c.mm.; haemoglobin, 92 per cent.; colour-index, 1.05; leucocytes, 5150 per c.mm.; these consisted of polymuclear leucocytes, 58 per cent.; lymphocytes, 36 per cent.; eosinophils, 4 per cent.; and transitional leucocytes, 2 per cent. No abnormal cells were seen, and no blood parasites discovered. A blood culture proved sterile and the Wassermann reaction negative. The blood serum was found to agglutinate *B. typhosus* in 1:32 dilution; this showed a sharp end-point and is of no significance, as the patient was inoculated with T.A.B. vaccine during the war. There was no agglutination of *B. dysenteriae* Shiga or Flexner, nor of paratyphoid A and B. The urine was of specific gravity 1000, contained neither albumin nor sugar, pus, or blood cells. Cultures of the urine were sterile. The feces contained no pathological bacteria or amebae.

Diagnosis.

The case was one of unexplained pyrexia lasting three weeks and associated with rigors at intervals. The first and most obvious diagnosis was that of malaria, as the patient had suffered from this complaint in 1920. The fact that he had had no return for more than six years, however, made it clear that this infection was very unlikely to be present. Moreover, no parasites had been found in the blood, and very large doses of quinine failed to produce any beneficial effect upon the temperature or general condition. Any septic conditions would seem to be ruled out by the persistent leucopenia and there was no evidence in the blood or stools of any amebic infection leading to a liver abscess.

A military tuberculosis of the lungs was unlikely as the condition of the patient remained good and radiographic examination of the chest failed to show any tuberculous lesions. Moreover, recurrent rigors are unusual in military tuberculosis. There remained those infections which are associated with leucopenia,

prolonged pyrexia, and rigors. The blood agglutination tests ruled out the typhoid and paratyphoid group of organisms. Dr. Manson-Bahr saw the case with me and suggested that the blood agglutination to the Malta fever organisms should be tested. He found a very strongly positive reaction. With *M. melitensis* complete agglutination occurred in dilution 1:540, while with the *B. abortus* Bang there was complete agglutination in 1:860. Blood cultures remained sterile up to three weeks. Further agglutination reactions obtained by Dr. Manson-Bahr from other strains of this group are conveniently recorded in Table I.

TABLE I.—Illustrating Results of Agglutination Reactions other than those Mentioned in the Content.

Organism	Serum dilutions.					
	1:50	1:100	1:200	1:400	1:800	1:1600
<i>B. melitensis</i> , Stock emulsion..	+++	+++	++	+	+	—
<i>B. melitensis</i> Group 1..	+++	+++	+++	++	+	—
Mediterranean <i>melitensis</i> ..	+++	+++	+++	++	+	—
Bovine <i>abortus</i> ..	+++	+++	+++	+++	+++	—
Human <i>abortus</i> ..	+++	+++	+++	+++	+++	—

Dr. G. T. Western kindly made an independent examination of the patient's serum and fully confirmed the results in every way. Blood cultures remained negative and there was no agglutination to any organism except *M. melitensis* and *B. abortus* Bang. Dr. Western found a positive complete agglutination to the former of 1:512 and partial up to 1:1024, while the *B. abortus* was completely agglutinated in dilution 1 in 1024 and partially up to 1 in 2048. There could be little doubt that the pyrexia was due to one of these two organisms. The cutaneous "melitene reaction" was tested. On the upper part of the left thigh an emulsion of *B. abortus* was injected intradermally while as controls, the skin was also injected with *Bacillus coli* and sterile broth. The results are given in Table II, and indicate a positive result for *B. abortus* infection.

TABLE II.—Illustrating the Results Obtained from the "Melitene Reaction."

Site.	Material injected intra-dermally.	Area of redness and exudation.	Time during which the erythema persisted.
Left thigh {	<i>B. abortus</i> .	1½ inch	7 days.
Right thigh..	Sterile broth.	1 "	24 hours.
	<i>B. coli</i> .	1 "	36 hours.

Source of the Infection.

There is little doubt that cow's milk supplied the source of infection in this case. The patient had never to his knowledge partaken of goat's milk, and no goats were kept in the neighbourhood of his farm. Inquiry, however, as to the occurrence of abortion amongst the herd of cattle kept on his farm proved fruitless and potent evidence in favour of the view that the infection had occurred through the medium of cow's milk.

The first abortion amongst the patient's herd of cattle occurred in January, 1926. This animal was sold a few days later. On Dec. 15th, 16th, and 17th, 1926, three more cows aborted, one of these being milked throughout the whole of the lactation period, and the milk during the latter months was used for household purposes. All three cows were sold prior to February, 1928. A heifer aborted in January, 1927, but this animal was never milked; similarly the milk of another heifer which aborted in January, 1928, was never consumed by any members of the household. In January, 1928, ten cows and heifers in calf were inoculated against *B. abortus* infection, whilst ten more were inoculated in June, 1928. It seems therefore most likely that infection

with the *B. melitensis* can be excluded and that the case was one of *B. abortus* infection in man.

Treatment and Progress.

A vaccine containing *B. abortus* and *B. melitensis* was prepared and inoculations commenced on July 12th. These were repeated on alternate days, the initial dose being 40 million bacilli; the maximum dose given on July 20th was 200 million. The strength of the intermediate inoculations is indicated on the temperature chart. There was no improvement in the patient's condition following these injections, and they were consequently discontinued. From August 10th to August 15th five injections of colloidal manganese were given and three yatroen pills were given daily. The patient gradually improved and continued to make good progress towards recovery. A slight degree of pyrexia, however, still persisted. Throughout the illness the pulse-rate varied from 80 to 120 and the patient's general condition remained good, and apart from general malaise and severe discomfort during the rigors he showed no abnormal symptoms or physical signs. The temperature gradually became normal, and since the end of September he has remained well and steadily put on weight. A suggestion was made that the patient might be benefited by being fed on the milk of a cow with a high agglutination against *B. abortus*. When, however, it was pointed out that these cows had been immunised by live cultures of *B. abortus* and eliminate large amounts of virulent *B. abortus* in their milk daily, the suggestion was not carried out.

Summary.

A review is made of the literature concerning *B. abortus* infection occurring in man and in animals, and the similarity between the *B. abortus* and *M. melitensis* and the diseases which they produce is noted. The seventh authentic case of *B. abortus* infection occurring in man in this country is reported, results of the investigations carried out in this case are recorded, and the progress made by the patient outlined.

Conclusions.

(1) In any case where exhaustive investigations have failed to discover the cause of a prolonged pyrexia, the possibility of *B. abortus* infection must not be lost sight of, and agglutination reactions against the *B. abortus* should be conducted. (2) The blood count in a case of *B. abortus* infection characteristically demonstrates leucopenia with a relative lymphocytosis. (3) Of the domesticated animals the cow appears to be the means of transmitting the infection to man in this country. Transmission of the infection by goat's milk in England has not been proved. (4) A history of abortion occurring amongst a herd of cows which supply the dairy products consumed by a patient should aid in the diagnosis of this disease. (5) The inoculation of pregnant cows with dead *B. abortus* is free of danger, but the practice of inoculating cows, even when empty and two months prior to service with live cultures of *B. abortus* is fraught with grave risks, and this procedure should be discontinued as it is known that 30% of the injected cows pass *B. abortus* out in their milk, and they may continue to do this for long periods (even years) following the original injection. The illness when it becomes established is prolonged, but the prognosis is good. (7) Various therapeutic treatment of this condition is of no value. Treatment is ineffective.

I have to acknowledge the assistance of Dr. Western and Dr. Wilson in confirming the agglutination reactions. I have also to thank Dr. W. Thomson, who sent me the vaccine, for his great assistance in obtaining the vaccine.

THE POSSIBLE EXISTENCE IN THIS COUNTRY OF DISEASE DUE TO INFECTION WITH *BRUCELLA ABORTUS*.

By H. HARRISON, M.B., D.P.H. MANCH.,

DEPARTMENT OF BACTERIOLOGY, UNIVERSITY OF MANCHESTER; AND

G. S. WILSON, M.D., M.R.C.P. LOND., D.P.H.,

READER IN BACTERIOLOGY AND IMMUNOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

CASES of human infection with *Brucella abortus* (*Bacillus abortus* Bang) have been described in the last five years by Orpen (1923-24) and Bevan (1925) in Southern Rhodesia, by Keefer (1924), Huddleson (1926), Carpenter and Merriam (1926), Carpenter (1926), and Belyea (1927) in the United States, and by Fical and Alessandriani (1925) and Viviani (1925) in Italy. A review of the cases reported up to February, 1927, has been furnished by Evans (1927). In this country no definite cases of infection have hitherto been reported. Duncan (1921), it is true, reported one such case, in which *Br. abortus* was recovered in pure culture from the blood, but as the patient had been a butcher in Southern Rhodesia it is probable that he had acquired his infection outside this country. Bamforth (1927), Wordley (1927), and Manson-Bahr (1927), however, have reported cases of undulant fever in which the patient's blood agglutinated *Br. abortus* or *Br. melitensis* to a titre varying from 1/160 to 1/2000, but they were not successful in demonstrating the infective organism. As infectious abortion of cattle is very common in this country, and as *Br. abortus* has been found in as many as 8.8 per cent. of mixed milks (Wilson and Nutt, 1926), it is not unreasonable to suppose that cases of active infection with this organism must occur. On the other hand, it is difficult to believe that if undulant fever were at all common in this country it should hitherto have remained undiagnosed. The suggestion therefore is that if *Br. abortus* does give rise to infection the clinical type of disease is as a rule different from that usually associated with infection due to *Br. melitensis*. A review of the reported cases of infection with *Br. abortus* lends colour to this suggestion. The case-histories are not typical of undulant fever. Instead of successive waves of fever with daily remissions, as in Malta fever, the temperature is continuous, irregular,

or paroxysmal. The main symptoms appear to be headache, lassitude, chilliness, and joint pains or "rheumatism." The onset is insidious, and the illness so mild that many cases remain ambulant even during the febrile stage. With such a course the diagnosis can be made only by bacteriological means. The duration of the illness is variable; it may last for only a few weeks or the patient may not be finally free from symptoms for several months.

Experimental Work.

In order to ascertain, if possible, whether infections with *Br. abortus* do occur in England, we decided to examine a number of blood sera for the presence of agglutinins to this organism. The work was carried out between April and October, 1927, at the Public Health Laboratory, Manchester. Two sets of sera were chosen: 1. Wassermann sera; these came from patients who were suspected of suffering from syphilis; only those sera giving a negative reaction were employed. 2. Widal sera: these came from patients who were suspected of suffering from enteric fever; only sera giving a negative agglutination reaction to *Bacillus typhosus*, *B. paratyphosus* A, B, and C, *B. aertrycke* (Mutton and Newport), and *B. enteritidis* Gœrtner were employed. By examining the Wassermann sera we hoped to gain some idea of the normal titre to *Br. abortus*; by examining the Widal sera we hoped to detect cases of abortus fever amongst the numerous cases of undiagnosed pyrexia from which the majority of these sera were derived.

Technique.—A strain of *Br. abortus* that had recently been isolated from a milk produced in the neighbourhood was seeded on to a number of agar plates, which were then incubated under lowered oxygen pressure at 37° C. for five days. The resulting growth was washed off with 0.5 per cent. phenolised saline, and diluted until in opacity it matched a suspension containing 700×10^6 *B. coli* per c.cm. This constituted our stock suspension, and was used throughout the whole of the investigation. When tested against a specific immune serum it agglutinated to the same titre as the homologous organism. The sera to be examined were diluted in saline and mixed with an equal volume of bacterial suspension so as to give final dilutions of 1/10, 1/20, 1/40, 1/80, and 1/160. The mixtures were incubated for 18 hours at 55° C. in a partly filled water-bath, and the results read against a brightly illuminated dark background. Serum and saline controls were put up each time. When agglutination was observed up to the 1/160 dilution the serum—if sufficient remained—was re-tested in a series of higher dilutions. The results were as follows:—

Wassermann sera examined	..	..	998
Wassermann sera examined from patients whose	..	..	
age and sex were known..	..	..	940
Sera reacting at 1/10 or higher	..	..	54
Sera not reacting at 1/10 or higher..	..	..	944
Percentage of sera reacting at 1/10 or higher	..	..	5.41

TABLE I.—*Showing Age and Sex Distribution of the Wassermann Series of Patients.*

No. = Total number. R. = No. of reactors. N.-R. = No. of non-reactors.
% R. = Percentage of reactors.

Age in years.	Wassermann sera.												
	Males.				Females.				M. and F. combined.				
	No.	R.	N.-R.	% R.	No.	R.	N.-R.	% R.	No.	R.	N.-R.	% R.	
0-10	13	2	9		10				20	19	5	17	10.5
10-20	13	2	9		12	2	10	16.7	55	5	50	9.1	50
20-30	13	2	9		12	11	1	91.7	265	17	248	6.4	294
30-40	13	2	9		11	6	5	54.5	274	11	263	4.0	303
40-50	13	2	9		69	61	8	88.4	171	10	161	5.8	240
50-60	13	2	9		32	31	1	96.9	106	6	100	5.6	119
60-70	5	0	5	0	15	1	14	6.7	41	1	40	2.4	46
70 and over	5	0	5	—	4	0	4	—	9	0	9	0.0	9
Total.	543	22	521	4.1	397	30	367	7.6	940	52	888	5.5	1032

From Table I. it appears that 5.5 per cent. of the population examined contained agglutinins at 1/10 or higher for *Br. abortus*; that the proportion of females

reacting was nearly double that of the males; and that, though the figures for some of the different age-groups are scanty, it seems that the younger the patient the more likely is his serum to contain agglutinins. It looks, in fact, as if there is a very gradual falling off in the proportion of reactors as age advances.

TABLE II.—*Wassermann Sera: showing the Titre of the Reacting Sera.*

1/10	1/20	1/40	1/80	1/160	1/320	1/640	1/1280	Δ ver. titre.
17	19	11	3	2	0	1	1	1/64

Table II. seems to show that a titre up to 1/40 is by no means uncommon, and is probably of little or no significance in the diagnosis of abortus fever. A titre of 1/80 is very much less common, and may be regarded as suspicious. The patients reacting at 1/80 were all males, aged 19, 22, and 25 respectively. No history of their illness was obtainable. Of the two reacting at 1/160, one was a male aged 38, from whom no history was obtainable; the other was a female, aged 47, with an indefinite illness lasting about six months. The patient reacting at 1/640 was a male aged 56, who was diagnosed as suffering from osteitis; the patient reacting at 1/1280 was a male aged 28, diagnosed as neurosis. It is very unfortunate that precise histories were not obtainable, but it is striking to note that of the seven patients reacting at 1/80 or over, six were males of between 19 and 56 years of age.

The results of the Widal sera were as follows:—

No. of sera examined					42
Ditto reacting at 1/10 or higher					11 = 26.2%
Males { Examined	28	Females { Examined	14		
Reactors	6	Reactors	5		
Age of male reactors				27, 28, 30, 41, 45, 54	
„ female „				15, 32, 44, 48, 52	

TABLE III.

1/10	1/20	1/40	1/80	1/160	1/320	1/640	1/1280	Aver. titre.
2	0	4	0	2*	0	1	2	1/336

* Neither of these sera was titrated fully; the titre may therefore have been higher than 1/160.

History of Patients with Titres of 1/160 and Over.

CASE 1.—Male, 45 years; ex-soldier; served for several years in Malta. Suffering from pyrexia of unknown origin. Temperature varied from 99° to 103° F. No rose spots, no diarrhoea, spleen not enlarged; some delirium. Titre 1/160, or possibly higher.

CASE 2.—Male, 36; employed in gasworks. Suffering from pyrexia of unknown origin. Temperature varied from 98° to 102·6° F. No rose spots; diarrhoea for three days; delirium for two days; spleen not enlarged. Titre 1/160 or possibly higher.

CASE 3.—Male, 41. Suffering from pyrexia of unknown origin. Temperature not higher than 101.2° F. No diarrhoea. spleen not enlarged. On fourteenth day of disease titre to *Br. abortus* was 1/40; on twentieth day titre had risen to 1/640.

CASE 4.—Male, 54; railway works manager. Drinks little milk, but eats much gorgonzola cheese. Not been abroad for nearly 30 years. Insidious onset about middle of April with general apathy, malaise, and chilliness; gradually getting worse. Temperature rose to 100°-102° F. in the evening and returned to normal in the morning. Sent for doctor on June 2nd. Temperature at 8.30 p.m. was 102° F. and pulse-rate 84. Patient sent to bed and temperature came down with gradually diminishing evening rises until in five days it reached normal. Blood serum on June 7th, 1927, negative to the typhoid-paratyphoid group, but agglutinated *Br. abortus* to a titre of over 1/320. General condition improved during next ten days. On June 17th, a second specimen of serum agglutinated *Br. abortus* and *Br. melitensis* (C4 and C6 strains*) to 1/1280. Patient went

**Er. melitensis* C1 was No. 893 } of Nat. Collect. of Type { Group I.

 " C6 " No. 891 } to Feustler and Meyer's { " III.

with the *B. melitensis* can be excluded and that the case was one of *B. abortus* infection in man.

Treatment and Progress.

A vaccine containing *B. abortus* and *B. melitensis* was prepared and inoculations commenced on July 12th. These were repeated on alternate days, the initial dose being 40 million bacilli; the maximum dose given on July 20th was 200 million. The strength of the intermediate inoculations is indicated on the temperature chart. There was no improvement in the patient's condition following these injections, and they were consequently discontinued. From August 10th to August 15th five injections of colloidal manganese were given and three yaten pills were given daily. The patient gradually improved and continued to make good progress towards recovery. A slight degree of pyrexia, however, still persisted. Throughout the illness the pulse-rate varied from 80 to 120 and the patient's general condition remained good, and apart from general malaise and severe discomfort during the rigors he showed no abnormal symptoms or physical signs. The temperature gradually became normal, and since the end of September he has remained well and steadily put on weight. A suggestion was made that the patient might be benefited by being fed on the milk of a cow with a high agglutination against *B. abortus*. When, however, it was pointed out that these cows had been immunised by live cultures of *B. abortus* and eliminate large amounts of virulent *B. abortus* in their milk daily, the suggestion was not carried out.

Summary.

A review is made of the literature concerning *B. abortus* infection occurring in man and in animals, and the similarity between the *B. abortus* and *M. melitensis* and the diseases which they produce is noted. The seventh authentic case of *B. abortus* infection occurring in man in this country is reported, results of the investigations carried out in this case are recorded, and the progress made by the patient outlined.

Conclusions.

(1) In any case where exhaustive investigations have failed to discover the cause of a prolonged pyrexia, the possibility of *B. abortus* infection must not be lost sight of, and agglutination reactions against the *B. abortus* should be conducted. (2) The blood count in a case of *B. abortus* infection characteristically demonstrates leucopenia with a relative lymphocytosis. (3) Of the domesticated animals the cow appears to be the means of transmitting the infection to man in this country. Transmission of the infection by goat's milk in England has not been proved. (4) A history of abortion occurring amongst a herd of cows which supply the dairy products consumed by a patient should aid in the diagnosis of this disease. (5) The inoculation of pregnant cows with dead *B. abortus* is free of danger, but the practice of inoculating cows, even when empty and two months prior to service with live cultures of *B. abortus*, is fraught with grave risks, and this procedure should be discontinued as it is known that 30 per cent. of the injected cows pass *B. abortus* out in their milk, and they may continue to do this for long periods (even years) following the original injections. (6) The illness when it becomes established may be very prolonged, but the ultimate prognosis is good. (7) Various therapeutic measures recommended in the treatment of this condition have proved to be of little or no value. Treatment by vaccines appears to be ineffective.

I have to acknowledge help from Dr. Manson-Bahr and Dr. Western and from Sir A. Castellani, who confirmed the agglutination results already obtained. I have also to thank Dr. W. Evans, my first assistant, for help in the preparation of these notes. Dr. J. R. K. Thomson, who sent me the case, has also been of great assistance in obtaining full clinical details.

THE POSSIBLE EXISTENCE IN THIS COUNTRY OF DISEASE DUE TO INFECTION WITH *BRUCELLA ABORTUS*.

BY H. HARRISON, M.B., D.P.H. MANCH.,
DEPARTMENT OF BACTERIOLOGY, UNIVERSITY OF MANCHESTER;
AND

G. S. WILSON, M.D., M.R.C.P. LOND., D.P.H.,
READER IN BACTERIOLOGY AND IMMUNOLOGY, LONDON SCHOOL
OF HYGIENE AND TROPICAL MEDICINE.

CASES of human infection with *Brucella abortus* (*Bacillus abortus* Baug) have been described in the last five years by Orpen (1923-24) and Bevan (1925) in Southern Rhodesia, by Keefer (1924), Huddleson (1926), Carpenter and Merriam (1926), Carpenter (1926), and Belyea (1927) in the United States, and by Ficai and Alessandrini (1925) and Viviani (1925) in Italy. A review of the cases reported up to February, 1927, has been furnished by Evans (1927). In this country no definite cases of infection have hitherto been reported. Duncan (1921), it is true, reported one such case, in which *Br. abortus* was recovered in pure culture from the blood, but as the patient had been a butcher in Southern Rhodesia it is probable that he had acquired his infection outside this country. Bamforth (1927), Wordley (1927), and Manson-Bahr (1927), however, have reported cases of undulant fever in which the patient's blood agglutinated *Br. abortus* or *Br. melitensis* to a titre varying from 1/160 to 1/2000, but they were not successful in demonstrating the infective organism. As infectious abortion of cattle is very common in this country, and as *Br. abortus* has been found in as many as 8.8 per cent. of mixed milks (Wilson and Nutt, 1920), it is not unreasonable to suppose that cases of active infection with this organism must occur. On the other hand, it is difficult to believe that if undulant fever were at all common in this country it should hitherto have remained undiagnosed. The suggestion therefore is that if *Br. abortus* does give rise to infection the clinical type of disease is as a rule different from that usually associated with infection due to *Br. melitensis*. A review of the reported cases of infection with *Br. abortus* lends colour to this suggestion. The case-histories are not typical of undulant fever. Instead of successive waves of fever with daily remissions, as in Malta fever, the temperature is continuous, irregular,

Clinical and Laboratory Notes.

ON THE

RELATIVE VALUE OF DIFFERENT MEDIA FOR THE DETECTION OF SMALL NUMBERS OF ANAEROBIC BACILLI AND THEIR SPORES.

By J. E. MARCHAL.

(From the Standard Department, National Institute for
Medical Research, Hampstead.)

THIS investigation was undertaken in order to determine the most efficient method of detecting small numbers of organisms or spores in sera, vaccines, or any substances to be administered intravenously or subcutaneously. Four organisms were used in the trials: *B. sporogenes*, *B. tetani*, *Vibrio septique*, and *B. welchii*. The tests were carried out with 24-hours cultures of the organisms, and again with spores obtained one or more weeks after implantation. The culture media used were:—

1. In ordinary test-tubes:

Glucose digest broth	} uncovered and covered with liquid paraffin.
" " " + asbestos	
" " " + meat	
" " agar shakes	

The same series made of peptone broth instead of digest broth.

2. In Theobald Smith's tubes:

Glucose digest broth.
" " " + asbestos.

Experiments with Implantation of 24-Hours Cultures.

A heavy growth of the organisms was obtained in a suitable medium such as glucose broth + asbestos or meat; 1 c.cm. of this was added to a tube containing 9 c.cm. of broth; from this 1 in 10 dilution further dilutions in tenfold steps were carried down until one of 1 in 1,000,000,000 was obtained.

oxygen was carried out in a steam steriliser. Series of nine tubes of each medium were taken, and each of them inoculated with the same amount of the various dilutions from 1 in 1,000,000,000 to 1 in 10. The size of the inoculum proved, after a number of comparative experiments, not to have any constant influence on the resulting growth, so it was decided to use a fixed amount—namely, 100 c.mm. of each dilution. Series of experiments comparing covered and uncovered media showed that, except in the case of simple glucose broth, the layer of paraffin was apparently only a slight advantage. It must be remembered that the other liquid media contained a piece of solid material which, as shown by Fleming, promotes the growth by allowing the organisms to collect and concentrate their chemical action in a small portion of the medium. For comparison between ordinary test-tubes and Theobald Smith's tubes we used, in the test-tubes, uncovered glucose broth, which had proved very inferior to the other media, and covered glucose broth + asbestos, which, together with the meat medium and glucose agar shakes, had given the best results. The Theobald Smith's tubes contained glucose broth or glucose broth + asbestos.

In no case did Theobald Smith's tubes show growth when implanted with higher dilutions than ordinary test-tubes containing covered glucose broth + asbestos. Their only advantage is that they would detect aerobes as well as anaerobes, but they are expensive and clumsy to handle. Up to this stage digest broth had been the basis of all our media; it was now thought that comparative tests should be made with peptone broth, and in the subsequent experiments, double series of covered broth + asbestos and glucose agar shakes were put up, one of which was made up with digest broth, the other with peptone broth.

Summary.

Digest broth and peptone broth were found to give very much the same results. When the whole series of experiments performed is analysed, including

1 or 3 i = 1, 2, or 3 irregularities in the sequence of positive cultures.

(a) = Theobald Smith's tubes.

Gluc. br. = glucose broth.

Spores.

The organisms were grown for a week or more on blood-agar shakes in Fildes and MacIntosh's anaerobic jar and a rich spore-formation was obtained. The growth was washed off the slope with a small quantity of broth, 1 c.cm. of which, added to the first tube, gave a 1 in 10 dilution. The same series of dilutions was used as with 24-hours cultures.

Technique.

The tubes containing the test media were placed in boiling water for at least 20 minutes, and inoculated immediately after cooling. For the Theobald Smith's tubes the preliminary heating to drive off dissolved

many not individually presented here, it is found that:—

In 20 experiments in which the value of media containing meat and asbestos covered with paraffin was compared:

In 11, asbestos = meat medium.
In 6, " > " "
In 3, " < " "

In 19 experiments in which the value of media containing asbestos and covered with paraffin was compared with that of glucose agar shakes:

In 8, asbestos = agar medium.
In 5, " > " "
In 6, " < " "

for a holiday, but felt so ill that he returned home after two or three days. Severe night sweats and occipital headache. Improved again. On June 23rd a third specimen of serum agglutinated *Br. abortus* and *Br. melitensis* C4 to 1/640 and *Br. melitensis* C6 to 1/320. A blood culture taken on the same date remained sterile. Patient was then afebrile. With the second specimen of serum an absorption test was carried out, using *Br. abortus* and *Br. melitensis* C4, C5, and C6. The result showed that *Br. abortus* was the only organism that completely removed all agglutinins from the serum; C4 and C5 removed nearly all the agglutinins, while C6 merely lowered the titre for *Br. abortus* and C4 by about 50 to 75 per cent.

CASE 5.—Male, 27; milker on dairy farm. Never been abroad. Never drunk goat's milk, but drinks three pints of raw cow's milk a day. Pyrexia of unknown origin; temperature rises to 102.5° F. in the evening and falls to between 99.5° and 101° F. in the morning. On fourteenth day of illness patient's serum agglutinated *Br. abortus* to 1/1280. Pyrexia subsided after another week, but further records of temperature were not available. Seven weeks after commencement of illness titre to *Br. abortus* was greater than 1/5120, to *Br. melitensis* it was only 1/1280; blood culture taken then was negative.

It is interesting to note that all the patients reacting at 1/160 or over were males. Whether this was the result of examining so few sera, or whether males are actually more liable to severer grades of infection with *Br. abortus*, is impossible to say.

Discussion.

We have examined 998 Wassermann sera; of these 5.5 per cent. agglutinated *Br. abortus* to a titre of 1/10 or higher. We have also examined 42 Widal bloods, all of which were negative to organisms of the typhoid-paratyphoid group; of these 26.2 per cent. agglutinated *Br. abortus*. The average titre of the Wassermann sera, coming from presumably apyrexia patients, was 1/64; the average titre of the Widal sera, coming from presumably febrile patients, was 1/336. Unfortunately, precise histories of the positive reactors amongst the first group were unobtainable, but in the second group all of those who agglutinated *Br. abortus* to 1/160 or higher were suffering from pyrexia of unknown origin, and in two of these cases the history is not unlike that of reported cases of abortus fever. It is remarkable that whereas in both groups the proportions of females to males reacting positively is nearly 2 to 1, 11 out of the 12 patients giving what we may consider a titre higher than that liable to be found in normal blood serum are males.

The evidence that we bring forward is sufficient, we consider, to suggest that *Br. abortus* is capable of infecting human beings in this country. Until positive blood cultures have been obtained, however, this suggestion must remain unproven. The conditions under which we received the sera for examination were such as to render direct access to the patient or even a detailed case-history extremely difficult. We had therefore no opportunity of making systematic blood cultures or repeated tests of the agglutinating power of the serum. It is for this reason that we are publishing our observations in their present incomplete state. We feel that if those who have the supervision of cases of undiagnosed pyrexia, of cases of suspected pulmonary tuberculosis in which tubercle bacilli cannot be demonstrated, and of cases presenting indefinite symptoms, particularly lassitude, headache, chilliness, and bone and joint pains with occasional rises of temperature, will take the opportunity of testing the serum against *Br. abortus* and of making systematic blood cultures—taking care never to discard the cultures before ten days—then the question whether true abortus fever does occur in this country will very soon be answered.

Summary.

1. 998 sera sent in for Wassermann testing and proving negative have been examined for agglutinins to *Br. abortus*; 5.5 per cent. agglutinated this organism to a titre of 1/10 or higher. The average titre was 1/61. The proportion of females to males proving positive was nearly 2 to 1. A titre of 1/40 is not uncommonly

met with, and is probably of no significance in the diagnosis of abortus fever.

2. Forty-two sera sent in for Widal testing and proving negative to members of the typhoid-paratyphoid group have been examined for agglutinins to *Br. abortus*; 26.2 per cent. agglutinated this organism to a titre of 1/10 or higher. The average titre was 1/336. The proportion of females to males proving positive was nearly 2 to 1.

3. Of 7 Wassermann sera agglutinating *Br. abortus* to 1/80 or higher, 6 came from males between 19 and 56 years of age. Of 5 Widal sera agglutinating *Br. abortus* to 1/160 or higher, all came from males between 27 and 54 years of age; all five of these were suffering from pyrexia of unknown origin. It is impossible to say from these data whether this preponderance of males showing evidence of active infection is fortuitous, or is indicative of a greater susceptibility on the part of males to the severer grades of infection.

4. The tentative conclusion is advanced that *Br. abortus* is probably capable of infecting human beings in this country; and it is suggested that blood cultures and agglutinin tests should be made on all cases of undiagnosed pyrexia and of indefinite, occasionally febrile maladies.

We wish to take this opportunity of thanking all those who have helped us in this, and particularly those who have kindly supplied us with information about patients under their charge.

Addendum.—An important article has just been published by Dr. M. Kristensen, of Copenhagen.† He examined 1177 Widal sera and found that 89 of them agglutinated *Br. abortus* to 1/100 or higher. Blood cultures were made from 20 of these patients, and in 13 of them an organism indistinguishable from *Br. abortus* was isolated. The technique used was to seed 3 to 5 c.cm. of the patient's blood into a fluid medium—preferably liver broth—incubate at 37° C. for 10 to 14 days in an atmosphere of 10 per cent. CO₂, and plate out at intervals on to serum or ascitic agar. Of the 89 patients 68 were males and 21 females; no patient was under 13 years of age. Clinically the picture was that of undulant fever, with sometimes severe sweating, localised pains, bronchitis, diarrhoea, or enlarged spleen. Infection occurred apparently from contact with aborting cows or from drinking raw milk or cream.

DANGEROUS DRUGS REGULATIONS.—On and after Jan. 1st, 1929, the following drugs, besides those which are already controlled, can be dealt in only by persons licensed or authorised by the Home Secretary: coca leaves, Indian hemp (including the resins, extracts, and tinctures), and preparations containing less than 0.1 per cent. of diacetyl-morphine (heroin). Applications for licences should be addressed to the Under Secretary of State, Home Office.

nurse introduced the infection and was the means of its dissemination in the wards concerned. The character of the membrane in the nurses seems worthy of special notice. They were similar inasmuch as they were of a thin filmy nature and not having the firm adherent features of the quite typical case (as occurred in the throats of the infected children). The clinical course in each nurse was benign and no very serious features developed. Prompt antiserum therapy was resorted to in Case 1, but in Case 2 serum was omitted and a late post-diphtheritic palsy occurred.

There can be no doubt, I think, that each case was true diphtheria. The circumstantial evidence of cases following and other points add confirmation to the bacteriological and clinical findings. We have, therefore, two instances of clinical diphtheria, in Schick-negative young adults, having a benign course and showing a "modified" membrane. How can these phenomena be accounted for in the light of modern knowledge? It would seem that in these instances we have persons who have a "basal" immunity insufficient to entirely prevent infection but with power to modify the disease—and this modification not only extending to the general illness but to the local lesion also—allowing the production of a modified tonsillar exudate. Regarding the question of apparent avirulence of the Klebs-Löffler bacilli strain from Case 2; is it to be believed that the virulence of the bacillus was temporarily modified in the environment of a Schick-negative person, and its virulence enhanced on passage in the children? (We have no certain knowledge whether the children infected were previously Schick-positive, but in no case had there been any recognisable previous diphtheria infection.) If this is so we may also say that the characters of the membrane were related to the virulence.

The Question of Virulence.

The whole question of the relation of Schick reaction to clinical work is now becoming more stabilised, and certain points are practically settled—e.g., that Schick-negative carriers of virulent diphtheria bacilli are very dangerous to non-immunes. There are still some unsettled points on virulence and avirulence relationships and possible changes under different environments.

The literature on the question whether an avirulent strain ever becomes virulent is large, but the bulk of the evidence is rather against the occurrence. The clinical evidence brought forward in this note at least suggests a variable virulence under different personal susceptibilities. From the epidemiological standpoint we may say that if a person, even though he be known to be Schick-negative, develops a sore-throat and shows morphological Klebs-Löffler bacilli, he should, at least be isolated and treated as a possible danger to others, even though experimentally the strain shows a low or undetectable virulence for animals. The Schick test and immunisation certainly have values in favour of the individual, but such personal immunity may, and sometimes does, have serious consequences for the multitude.

These points can have no greater importance than for the medical officer concerned with infectious disease in a children's hospital.

THE OSLER CLUB.—A meeting was held on Dec. 7th in honour of the sixtieth birthday of Dr. Max Neuburger, professor of the history of medicine in the University of Vienna and corresponding member to the Osler Club for Austria. The foreign secretary spoke of Sir William Osler's first acquaintance with Prof. Neuburger and reminded the meeting that Osler was responsible for the English publication of the "History of Medicine" in 1910 to which he contributed a preface. Dr. J. D. Rolleston paid a tribute to Prof. Neuburger as a medical historian, emphasising the wide range of subjects covered by his work. With this tribute Sir D'Arcy Power associated himself. Messages were read from the Austrian Legation in London and from Prof. Castiglioni, the corresponding member for Italy. An opportunity was given to see an exhibition of Prof. Neuburger's published writings. The remainder of the evening was devoted to the work and life of Malpighi, the tercentenary of whose birth is celebrated this year.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OTOTOLOGY.

A MEETING of this Section was held on Dec. 7th, with Mr. SOMERVILLE HASTINGS, the President, in the chair. Before the usual discussion on clinical cases there was a discussion on

MENINGITIS.

Mr. G. J. JENKINS said he had not much to add to the report which he submitted to the International Otological Congress at Paris in 1922, though some minor details he would now describe somewhat differently. He had insisted on the importance of distinguishing two groups of cases: one in which the infection was primarily of a trabeculated part of the subarachnoid space; the other in which the cisterna pantis was primarily infected. Appreciation of this greatly helped an understanding and recognition of the early symptoms of various types of meningitis, as well as assisting the rational treatment of the disease. Some cases of meningitis, even if there were micro-organisms in the cerebro-spinal fluid, had been known to recover after one or two lumbar punctures. This, he considered, proved conclusively that if the surgeon could give some degree of help the cerebro-spinal fluid might overcome the infection when it would otherwise fail to do so. In many cases of meningitis the organisms had not reached the subarachnoid space, and the meningitis was due to infection in close relation to the outer surface of the dura. In these patients a good result would follow the complete removal of the external inflammation. But it was only in the very early cases that one could be content with this procedure. The changes in the cerebro-spinal fluid could only be assessed in relation to the clinical features. There was a doubtful stage between the very early and the very advanced infections. He despaired of being able to reduce this doubtful group. He was inclined to treat them as probable infections of the subarachnoid space. Some might believe that results from surgical interference in such cases would not be so good as if they were left alone, but the speaker considered that if great care were taken in cleansing, after completing the external operation and before opening the subarachnoid, the risk to the patient was much less after the operation than if he were left without this further step. The meninges required drainage from the point of maximal infection, and the flow of normal cerebro-spinal fluid over the infected area must be encouraged.

For many years the following treatment had been carried out at King's College Hospital in cases of septic meningitis which appeared to need drainage, especially those secondary to septic labyrinthitis. Neither atropine nor morphia was given. The theatre staff and instruments were ready before the anaesthetic was administered; either ether or gas and ether was used. Iodoform was washed free of the perchloride, which had added to it modified Locke's solution. The anaesthetised patient was placed on the table on his side, and 5 or 6 c.cm. of cerebro-spinal fluid were drained off by lumbar puncture and given to the pathologist, who did a quick cytological and chemical examination. The patient was then turned on to his back, and the superior and inferior labyrinthotomy operations were completed. Tissue and mucous membrane likely to be grossly infected must be removed. The wound was syringed out with hydrogen peroxide and saline, then thoroughly syringed with a 2 per cent. alcoholic solution of iodine. A fine needle was passed into the labyrinth and the interior well doused with the iodine solution. By this time the pathologist's report would have been received, and the surgeon could decide whether or not drainage was necessary. Before anything further was done the patient was again rolled on to his side and a lumbar puncture was done, only a drop or two of the fluid escaping. Next the

Several interesting and important points come to mind on thinking over these two groups of cases. In the first place, it seems that in each instance a

Reviews and Notices of Books.

AN INDEX OF SYMPTOMATOLOGY.

By Various Writers. Edited by H. LETHBRIDGE TIDY, M.A., M.D. Oxon., F.R.C.P. Lond., Assistant Physician to St. Thomas's Hospital; Consulting Physician to Royal Northern Hospital. Bristol: John Wright and Sons, Ltd. 1928. Pp. 710. 42s.

THIS, the latest addition to the well-known "Index" Series, is worthy of its predecessors. In general design it resembles them, in that diseases are arranged in alphabetical order throughout the book. Symptoms do not appear as headings, nor are they classified in the index. Every branch of medicine and surgery is covered, including dermatology, gynaecology, tropical diseases, and diseases of the eye, ear, and throat. Only very rare conditions are omitted, the descriptions given being designed to portray a typical case of the disease in question, and minor and unimportant variations are either omitted or dealt with very briefly.

The object aimed at has been to draw from the purely clinical aspect a clear and graphic picture of all diseases for the guidance of a practitioner unfamiliar with, or in doubt about, a particular condition; and to enable the student to obtain a vivid conception of the disease, so that it may remain imprinted on his memory. That this object has been attained there can be no question. Each article has been written by an expert in that branch of medicine, and could hardly be made more lucid or concise: those sections dealing with the nervous system are outstanding in these respects. In conditions such as diseases of the skin and tropical diseases, which are seldom seen in this country, or in which it is particularly difficult to supply a clear mental picture of the appearance by words alone, the descriptions are supplemented by excellent and well-chosen illustrations, charts, or diagrams.

In accordance with its title the book deals not at all with differential diagnosis, and only the most essential and characteristic chemical and pathological changes are mentioned: thus no reference is made to electrocardiography, and no attempt is made to describe even the simplest of clinical pathological tests. The proportion of space allotted between the various classes of diseases is evenly maintained. At first sight it might appear that tropical diseases had been given rather more than their fair share: the description of other conditions is in no way curtailed.

The book will prove of value chiefly to the student on account of its comprehensive range and the clearness and brevity of the descriptions of the clinical picture. For the practitioner who wishes to use it as a book of reference in differential diagnosis it is less suitable; but he will be able to check a provisional diagnosis by consulting the account here given of the condition and comparing it with his own observations. The book is well produced.

PHOTOMETRIC CHEMICAL ANALYSIS.

Volume I. *Colorimetry*. By JOHN H. YOE, Ph.D., Professor of Chemistry, University of Virginia. London: Chapman and Hall, Ltd. 1928. Pp. 771. 42s. 6d.

THIS work is particularly interesting, for it indicates an entirely new departure in the methods of analytical research. For many years colorimetric methods have been regarded with a certain amount of disfavour by chemists, who have gone out of their way to adhere to the so-called classical methods—volumetric and gravimetric analysis. A certain number of estimations, however, could not be made by these means and therefore colorimetric methods were introduced; but the accuracy of the results obtained was not always

accepted. Perhaps one of the reasons why colorimetry has been unpopular with the pure chemist is the wholesale adoption of these methods by the biochemist, a person who has always been regarded with a certain amount of suspicion by the pure chemist. Unfortunately, the suspicion is not entirely unjustified, since some of the work published in this field has not been properly controlled. The careful work, however, of accurate investigators, like Otto Folin and many other distinguished analytical biochemists, has done a great deal to dispel these prejudices, and now colorimetric methods are recognised as being thoroughly reliable and accurate. We welcome, therefore, this volume which is devoted to colorimetry, and look forward to reading its companion which will be concerned with nephelometry.

The work opens with a chapter on general principles, followed by what must be the fullest description ever given of practically every type of colorimeter. The third and fourth chapters are devoted to the methods used in calculating the results, and include a particularly useful section on calibration and correction curves: the latter are very important, a fact which is not realised by the majority of workers. Prof. Yoe goes carefully into the whole question of the deviation from the theoretical relationship between concentration of unknown specimens and intensity of colour, and devotes much attention to the method of expressing these relations in formula, dealing with Beer's law in full. Everyone who uses a colorimeter should study this chapter. The fifth chapter, which deals with errors in colorimetry, is also admirable, and is followed by a section on stabilisers which contains many helpful tips. General directions for using a precision colorimeter are supplied by Dr. P. A. Kober, whose work in this field is well known. The remaining sections of the book are devoted to the actual methods for the determination of elements and various organic and inorganic substances, and it is safe to say that anyone following the methods given would be able to estimate any one substance in any other. The determination of metals, hydrogen-ion concentration, and organic substances, including urea, is discussed in full. The directions are sufficiently detailed to preclude any necessity for referring to other works.

The section upon the methods of blood analysis is well written, but the author does not appear to have had much practical experience in this particular branch. For instance, he gives the details for determining the blood-urea by the Folin-Wu distillation method; those who have tried to carry out this method following the original description have been baffled by the intractable frothing that occurs, to which no reference is here made. However, no man could reasonably be expected to have practical knowledge of the whole of the analytical procedure described in this book, which has evidently been prepared with very great skill and care.

DIAGNOSIS FROM INSPECTION ALONE.

Diagnostik mit freiem Auge. Endoskopie. Third edition. By Dr. EDUARD WEISZ, Pilsen. Berlin and Vienna: Urban and Schwarzenberg. 1928. Pp. 184. M.10.

THE first edition of this book appeared in 1923, the author having worked for 20 years at the method he describes before committing it to print. His "intercostales Sprechphänomen" was discovered accidentally during compass tests on the skin, in performing which he asked patients to state whether they felt one point or two. Their answers produced visible impulses in the intercostal spaces, and this he named the speech phenomenon.

At first it seemed to be a matter purely of academic interest that the "speech impulse" could be seen everywhere over the intercostal spaces except for the inner part of the precordium and two small bounded areas over liver and spleen, the "Leber- und Milzinsel." However, when the author discovered that the phenomenon was present over fluid but absent

opening into the internal auditory meatus was made through the inner wall of the labyrinth by the method of West and Scott. When the flow of cerebro-spinal fluid had been established, the lumbar puncture needle was connected with the reservoir of modified Locke's solution, with a fluid head of about 18 inches. When a few ounces of Locke's solution had passed through, the serum, carrying about grs. 8 of specially prepared iodoform, was injected by means of the lumbar puncture needle, and the Locke's solution was again allowed to flow until the fluid was returned clear at the ear. The wound was lightly packed with specially prepared iodoform gauze. Usually the patient, on being returned to bed, was given bromides and glucose by the rectum. As much fluid as possible should be given, also glucose. Digitalis and ephedrine seemed to produce most improvement. The sedatives mostly used were bromides and paraldehyde. If the cerebro-spinal fluid ceased to come away within 24 hours, and the patient seemed to be going back, the surgeon should seek to re-establish the drain; it might be possible to do this by the pre-cerebellar route. Plain horse serum had been used as a vehicle for the iodoform.

Mr. Jenkins next dealt with the value of maintaining a positive pressure of the cerebro-spinal fluid when operating on a septic region which communicated with the subarachnoid space. He said that if it should be necessary to operate in a septic area through which there was a leakage it was an advantage to have the cerebro-spinal fluid under positive pressure and flowing continuously rather than ebbing and flowing in the bottom of the wound.

Speaking on the leakage of cerebro-spinal fluid from the region of the ear, he said this was not frequently met with, but it was a cause of anxiety. He recalled three such cases in patients with temporo-sphenoidal abscess. In two of them the leakage occurred during the process of healing a few days after the abscess was opened. In the third leakage began some weeks after apparently sound healing. When there was leakage for a few days after the abscess was opened one could only keep the part clean and use iodoform gauze until granulation closure took place. When the leak occurred at a late stage a plastic operation should be done—i.e., moving a large flap of the temporal and sterno-mastoid muscles over the leaking area. He described briefly the three cases he referred to.

Mr. T. B. LAYTON spoke of so-called

Otitic Meningism.

His purpose, he said, was to deal with early cases which were on the way to established meningitis. At an early stage the physician was often doubtful whether the symptoms—headache, twitching, convulsions, head retraction, rigidity of trunk and limbs—were due to toxins which had got into the cerebro-spinal fluid or were the early indications of meningitis. His own view was that there was no such definite condition as meningism; and that, even if there were, it was sound policy to regard the symptoms as indicating an early stage of meningitis. The fluid at this stage would most probably show some cytological change, even if it did not contain organisms. Rigidity of the neck was, to the aural surgeon, a very definite danger signal. By the time the abdominal and other reflexes were affected the patient had passed to a stage in which his chance of recovery was small. Every patient with ear trouble who had rigidity of the neck should, he urged, be regarded as having meningitis, and lumbar puncture should not be done, because of the risk of sucking organisms from the ear to the region of the foramen magnum. He described several critical cases and his methods of dealing with them.

Mr. E. D. DAVIS spoke on the

Morbid Anatomy, Prevention, and Early Diagnosis of Otitic Meningitis.

The dura mater, he said, resisted the spread of infection from local cranial suppurations to the

meninges and brain, but it was weakened at the points where nerves and vessels penetrated it and at a cranial suture. Such penetration occurred through the petrous bone; hence otitic meningitis was usually basal, and the suppuration was found in the basal cisternae and in the posterior fossa. When it had extended to the basal cisternae satisfactory drainage was almost impossible; therefore it was important to make the diagnosis before the inflammation had reached this site. When the path of infection was through the internal ear transabyrinthine drainage by the internal auditory meatus and through the inner wall of the mastoid antrum should be done early. When infection spread by the lateral sinus the posterior fossa should be drained, both in front of and behind the lateral sinus. Irrigation he did not view with favour, as it was liable to spread infection.

Acute suppuration of the middle ear or mastoid following scarlet fever had been followed by meningitis. The same could be said of measles and the acute hæmolytic streptococcal infection in children of sudden onset and rapid development. When after a mastoid operation, pain for which there was no obvious reason, headache and temperature persisted for more than two days, a careful investigation ought to be made and the mastoid reopened. In quite a considerable number of cases meningitis had followed an exacerbation of a chronic suppuration or cholesteatoma of long duration; and in these the path of infection was often through the internal ear. In a large number of cases of meningitis following chronic suppuration symptoms and signs of labyrinthitis were present. These called for prompt action.

In conclusion, Mr. Davis declared that he had not regretted having drained the meninges too soon, but there were many cases known to him in which that procedure was left until it was too late to be of benefit.

A full discussion ensued, in which the following took part: Mr. E. Watson-Williams, Mr. F. W. Watkyn-Thomas, Mr. Holt Diggle, Dr. Dan McKenzie, Mr. M. Vlasto, Mr. J. Harper (Glasgow), Mr. Broughton Barnes, Mr. Sydney Scott, Mr. Musgrave Woodman, Mr. H. V. Forster (Liverpool), Sir James Dundas-Grant, Mr. T. B. Jobson, and the President.

New Inventions.

A NEW LANCET FOR OPENING A PERITONSILLAR ABSCESS.

THE difficulties which one often experiences in opening a peritonsillar abscess are only too well known. The instrument here illustrated, which is a modification of the well-known blood-letting lancet, has proved, to me, very reliable. It consists of a

long barrel into which fits the lancet, the length of which is regulated by unscrewing the barrel. By pulling the handle the lancet is made to disappear in the barrel, and at the same time a spring is compressed by a special device which keeps the lancet under tension in the desired position; the tension itself can be regulated. By pressing the handle the action of the spring is released and the lancet let loose with considerable force, thus producing a sharp and instantaneous cut. The manipulation of the instrument is very simple.

Messrs. Charles King, of Devonshire-street, London, W., are the makers.

Harley-street, W.

IMPORTATION OF CHEMICALS.—The Treasury have made an Order continuing till June 30th, 1929, the exemption from duty of R. acetone, acetone fermentation, acetone synthetic, and radium compounds.

THE LANCET.

LONDON: SATURDAY, DECEMBER 29, 1928.

THE KING'S ILLNESS.

WE are happy to believe that HIS MAJESTY THE KING is now making slow but steady progress towards recovery. A week ago an official statement issued by his doctors through our columns spoke of dangerous phases in the illness having been surmounted and of increasingly solid grounds for hope of recovery. On the following afternoon the Regius professors confirmed this opinion with the statement that the KING's progress is now established on a firmer basis. Day by day since then the local and general condition have improved, natural sleep has been restored, and the desire for food is returning. A significant sign of relaxed anxiety was the issue of a single daily bulletin on Sunday last. It may yet be too soon to speak of convalescence in view of the exhaustion which still remains as the sequel of broncho-pneumonia, empyema, and septicæmia, an evil triad which would have taxed any constitution however young or sound. No one but a medical man or a nurse knows the tediousness of recovery in these cases—the daily ups and downs among which it is hard to distinguish the slow gradual improvement. But convalescence is now in sight, and the relief has been enough to make the Christmas season more solidly and quietly happy, within and without the Palace, than would have been deemed possible earlier in the month.

THE CAUSATION OF MYOPIA.

SHORT-SIGHTEDNESS in young children is an elusive problem. Many have been the theories to account for the fact that whereas in the majority of individuals the growth of the sclerotic coat of the eyeball is approximately adapted to the purpose of focusing distant objects on to the retina, among the minority where this is not the case there are some in whom the sclerotic is unduly stretched during the early years of life so that accurate focusing can only be obtained by the use of concave lenses. Sir ARTHUR KEITH was altogether right when, a few years ago,¹ he termed myopia a disorder of growth and attributed it to a faulty reaction of the fibroblasts of the sclerotic to the stresses to which they are subject from intraocular pressure during the period of growth. This, no doubt, is a true way of putting it, and the factor of heredity, which in certain families is very prominent, obviously has to do with a defect

in the process of growth. But though this primary cause exists in all myopes, and in some of them—especially cases of high myopia beginning in pre-school years—may be of such importance as to put all secondary causes into the shade, it by no means follows that all other causes may be ignored, or that we should take up a fatalistic attitude with regard to the mitigation of myopia by hygienic measures. That the constant wearing of accurately prescribed glasses itself has a favourable influence in retarding or stopping the myopic process is a belief held by many ophthalmic surgeons of very wide experience in this matter, though we know of no statistics actually proving that such is the case. Of the various secondary causes to which the phenomenon of increasing myopia has been attributed the one which has received most attention is prolonged convergence of the eyes on any near work, which is supposed to involve an increase of pressure by the external muscles of the eye and especially the superior oblique. Unfortunately for this theory it has never been proved that the pressure of the external muscles actually does increase intraocular pressure. More probable is the theory that the chief secondary cause of myopia is venous engorgement, and since this would naturally result from prolonged stooping of the head and neck, such as most forms of work at short range entail, and since it is often especially noticeable in school-children, the hypothesis seems to be a reasonable one. Twenty years ago Prof. GEORG LEVINSON, of Berlin, laid stress on this factor in the causation of myopia, and since that time he has attempted to reinforce his view by experiments on young apes by keeping them in the horizontal position, the result of which was not only to make them decidedly myopic, but also to produce the fundus changes typical of myopia in man. In a recent paper² he states that these experiments have lately been repeated and confirmed in Java by W. F. R. ESSED and M. SOEWARNO. Of seven apes experimented on, five became myopic, while the refraction of three control animals remained unchanged. In two of the animals experimented on a myopic crescent was produced, while in a third there was venous hyperæmia. The eyes were excised and sent to Prof. LEVINSON, who confirmed the findings by pathological examination. The proportion of animals in whom myopia was produced artificially (70 per cent.) contrasts with the 16 per cent. in which myopia is said to be normally present. By these experiments Prof. LEVINSON claims to have provided an irrefutable proof of his theory. To some this claim, based on such comparatively small evidence, may seem to be rather bold; nevertheless the truth of the theory is highly probable. So far as the experimental evidence goes, the most striking point is the artificial production of an myopic crescent in two monkeys. It has been objected that the myopic crescent is no proof of myopia, as it is occasionally seen in eyes that are not myopic. The answer to this is that the typical myopic crescent is not congenital, but is the result of the stretching of the eyeball during the period of growth. If the process is started in an eye originally hypermetropic it may never proceed so far as to render it myopic, but may only lessen the degree of hypermetropia. This point is well explained in a recent article³ by A. SORRASKY on the development of myopia.

³ British Jour. of Ophthalmology, December, 1928, p. 611.

over consolidated areas, he was able to use it in differential diagnosis, and found that it helped him in dealing with interlobar empyema. It is also, in his hands, the means of diagnosing "mit freiem Auge," the upper limit of splenic and hepatic enlargements, since the intercostal spaces over these viscera remain immobile during the test. In fibroid lung or other conditions causing retraction of the lung from the heart the speech phenomenon disappears from the outer part of the præcordium. The author's "Schnupfphänomen" is used especially to mark out the diaphragm; its adoption in our hospitals would doubtless provide merriment for clinical clerks. The application of the speech phenomenon to the abdomen brings out immobile quadrants which correspond to areas of peritonitis. This is surely of academic interest only. The photographs illustrate the signs extremely well, and the diagrams are clear.

For ourselves we would hesitate to pronounce an opinion on the value of Dr. Weisz's method without having taken out a course of instruction in it at Bad Pistyan.

RADIOLOGY OF THE HEART.

Radiologie du cœur et des vaisseaux de la base. Fourth edition. By H. VAQUEZ, Professeur à la Faculté de Paris, Membre de l'Académie de Médecine, Médecin de la Pitié; and E. BORDET, Chef de Laboratoire à la Faculté de Médecine de Paris. Paris: J. B. Baillière et Fils. 1928. Pp. 500.

In the fourth edition of their deservedly popular work on the radiology of the heart Prof. Vaquez and Prof. Bordet have included a section dealing with the aorta and the pulmonary artery which had previously been treated in a separate volume. In discussing the relative merits of teleradiography and orthodiagraphy the authors express a preference for the latter method; they admit that it must introduce the personal factor, but maintain rightly, in our view, that in skilled hands it is capable of yielding more information. For this reason, presumably, very few actual photographs are reproduced as illustrations. This is unfortunate, for a good radiogram indicates in a way which no diagram can do some of the difficulties of interpretation with which the beginner is confronted when he attempts to read a film for himself. The chapter dealing with aortitis will prove of special value to the clinician, for it is in conditions where the other objective evidence is inadequate that radiology may serve to clinch the diagnosis. As the authors point out, this lesion may manifest itself merely by an increase in density of the aortic shadow without any increase in the calibre of the vessel, and considerable experience is required if the picture it presents is to be properly interpreted.

ERYTHEMA NODOSUM.

By J. ODERY SYMES, M.D., Consulting Physician to the Bristol General Hospital. Bristol: John Wright and Sons, Ltd. 1928. Pp. 72. 5s.

THIS dainty and compact monograph, based on a study of 250 cases seen by the author during a period of 30 years, is another plea for the recognition of erythema nodosum as an acute specific fever. The author adduces evidence of the communicability of the disease, its occurrence in epidemic outbreaks, and its seasonal incidence. The chart showing the sharp maximum of seasonal incidence in April is particularly noteworthy. The further features of the acute specific fever—namely, its definite and orderly sequence of events during the illness and the place of the malady among the diseases like influenza and poliomyelitis—are cogently dealt with. Of special interest are certain histological findings illustrated by plates. From these the author concludes that the lesion typically seen in erythema nodosum is an acute and widespread arteriolitis in the subcutaneous fat. A soluble toxin is suggested as the

causal agent. In the slides, which the author examined in large numbers, no evidence of a tuberculous lesion was found. Giant cells were often seen, but they are regarded by Dr. Symes as fat-phagocytes. The book is a personal record of observations, but the author makes due acknowledgments to London, who in 1905 published a very similar monograph in which he coined the term "Nodal Fever" as a synonym for erythema nodosum.

The difficult problem of the relationship between erythema nodosum and tuberculosis is stated rather than solved. In 19 out of a series of 102 cases under the author's supervision tuberculosis in some form or other was detected. This is in agreement with the general experience that a tuberculous lesion is associated with erythema nodosum in about 20 per cent. of all cases. An estimate of the significance of this fact in the matter of prognosis, and a clear account of such treatment as is called for in erythema nodosum, concludes a pleasantly written little book.

AN INTRODUCTION TO BIOPHYSICS.

Second edition. By DAVID BURNS. London: J. and A. Churchill. 1929. With 116 text-figures. Pp. 580. 25s.

MANY people have thought and think that the object of physiology is to explain life by chemistry and physics; it is an intelligible point of view, and Prof. Burns shows how it may be applied to the study of the working of the human body. Those who hold a different faith and are "debauched with the so-called science of biology" would also do well to read his book with as much sympathy as they can command; they will find a great deal of interest in it and a determined effort to apply general principles to the whole of human experience. The chief objection to the work is that it is not well written, and the argument is often confused and amorphous. The account of chlorophyll and the storage of energy, for example, could have been put much more clearly, and the paragraph on the standard deviation on p. 472 is partly unintelligible, and where intelligible not strictly accurate. In the section on the energy of growth (pp. 476 ff.) it seems that by "young animals" Prof. Burns must mean, "young warm-blooded animals," but he does not say so, and the earnest student can discover what "Rubner's second law" is only by going via the index to p. 492. The same kind of petty difficulties are present throughout the book, and it needs a more pedantic revision for its third edition.

MODERN PUBLIC CLEANSING PRACTICE.

Its Principles and Problems. By A. L. THOMPSON, M.Inst.M. and C.E., M.R.S.I., Cleansing Superintendent to the Motherwell and Wishaw Burgh Council. London: The Sanitary Publishing Co., Ltd. 1928. Pp. 201. 10s. 6d.

THIS book covers adequately the whole range of topics germane to the collection and disposal of refuse. It is concisely written, packed with information from the first chapter to the end, and contains numerous illustrations, nearly all excellently selected and reproduced. For the convenience of students appropriate questions are set at the end of each chapter, and the last page consists of a list of the works consulted. The methods of storage, collection, and disposal of refuse are clearly dealt with, and the advantages and disadvantages of each discussed in a very practical manner. Valuable information is given regarding land reclamation schemes and their management, with particular reference to the Bradford method. The chapter on street cleansing contains a useful discussion of this important subject.

Mr. Thompson has produced an excellent book of reference for all members of the public health services and a reliable guide for the student.

sted and Schiødt suggest that failure to acidify urine sufficiently is one of the reasons for these comparatively poor results, and they think that some ants may be incapable of secreting a more strongly urine because they form too much ammonia. ammonia formed on cleavage of the hexamine, decomposition of epithelial cells and leucocytes. the products of bacterial growth may all tend to interact urinary acidity. One reason why their are not as good as those of other workers they suggest, be that they allowed plenty of and they give reasons for thinking that a fluid intake should make acid disinfectant more efficient.

WARNING TO STRONG SWIMMERS.

A. Young, director of the Medical Research of the Gold Coast, was a particularly expert and before his death from yellow fever last wrote an article¹ suggesting a possible cause of surf-bathing. In not a few autopsies on swimmers found washed up on the beach Dr. Young found that the lungs were aerated and there was distension of the stomach, but this organ occasionally showed distension. He was in the habit of attributing the cause of death as heart failure from asphyxiation, but a paper on hypochlorhydria² having suggested to him that the air-swallowing which took place while swimming might lead to distension of the stomach to lead to asphyxiation. In order to swim out to sea breakers it is necessary to dive on the surface breathing is a matter of the right moment and dodging the waves. It is therefore necessary to hold the breath for periods and to breathe in quick gulps. While these gulps may themselves contain a small amount of air-swallowing, Dr. Young is more probable that air entered the lungs while the swimmer was under water. After the swimmer held against exertion for a certain time, the respiratory centre refuses to contract the expiratory muscles contract and a bit, and air is swallowed. Even though a deep breath had been noticed that there was a feeling of nausea and a curious distension. Eructation gave some relief; it had to be repeated to restore well-being, and there was a feeling of both from his own experience. Both from his own experience and from findings Dr. Young attributes the distension of the stomach to cardiac failure. As he gives additional advice "not to swim so much the time as to take up, so that a feeling of distension. If the swimmer is not under water, this is the best way to avoid the

blood is very rapid; R. A. Hatcher and H. Gold could not detect its presence in individual specimens 30 minutes after oral or intramuscular administration. It is not merely excreted, for only 25 per cent. can thus be accounted for, the rest being broken up into simpler substances, a process for which the liver seems to be largely responsible. W. Kirschbaum has produced malarial infection by injecting blood which had been set aside for 24 hours after being mixed with quinine to the extent of 1 in 10,000, a concentration far greater than has ever been maintained in circulating blood. Again, in certain cases which they investigated, W. Ramsden, I. J. Lipkin, and E. Whitley found the quinine content of the blood to be highest, and cinchonism greatest, in those in whom parasites persisted longest. Clearly, then, quinine in itself is not plasmodicidal. But of the effect of quinine in curing malaria there is no question at all, and we must suppose that it exercises its striking action in some indirect way. We have to recognise that intravenous injection does not act by suddenly making available a large amount of parasitocidal substance. And, if the liver is the organ where quinine is not only most rapidly snatched from the circulation but most effectively turned into the plasmodicidal substance—whatever that may be—then intravenous medication does not seem to lead to the desired result as directly as administration via the mouth and portal vein. Accurate observations of the efficiency of intravenous quinine medication are due to British observers headed by J. W. W. Stephens in Liverpool and H. W. Acton in India. The latter have shown that with it the maximum disappearance of plasmodia from the blood occurs within the first 24 hours, whereas with oral administration it takes place in the third 24 hours. But there is no evidence that actual disinfection is more readily obtained by one method than with the other, while the potential depressant action of intravenous quinine has been amply proved in India by R. McCarrison and J. W. Cornwall and by U. N. Brahmachari. Moreover, if any of the drug spill into the surrounding tissues these will slough, whilst thrombosis, so well established as occurring after its injection into varicose veins, has been reported even in healthy ones. Thus the intravenous route should probably be reserved for cases in which speedy action is essential—e.g., when there are urgent cerebral symptoms or when a swarm of subtertian parasites in the peripheral blood presages their onset—or in which the stomach refuses to retain the drug. The quinine should be introduced slowly, in considerable dilution, and in moderate doses, guarded if necessary with adrenalin; the blood pressure should be closely watched, and administration must be strictly aseptic. Intravenous quinine may in this way with reasonable safety be made available for those few special conditions in which its value has been fully demonstrated.

THE IDEAL ANNUAL HEALTH REPORT?

THE New York State Department of Health publishes every Monday a four-page sheet called *Health News*. Under the heading "Which Kind of an Annual Report is Yours?" a writer in this periodical classifies annual reports as surveys and obituaries. The latter are defined as recitations in a eulogistic, but monotonous, way of the deeds of the past. They are merely as records which are fed only if they demands. The survey, on the other hand, is a record of the things which are sharply by the better of the future.

over consolidated areas, he was able to use it in differential diagnosis, and found that it helped him in dealing with interlobar empyema. It is also, in his hands, the means of diagnosing "mit freiem Auge," the upper limit of splenic and hepatic enlargements, since the intercostal spaces over these viscera remain immobile during the test. In fibroid lung or other conditions causing retraction of the lung from the heart the speech phenomenon disappears from the outer part of the præcordium. The author's "Schnupfphänomen" is used especially to mark out the diaphragm; its adoption in our hospitals would doubtless provide merriment for clinical clerks. The application of the speech phenomenon to the abdomen brings out immobile quadrants which correspond to areas of peritonitis. This is surely of academic interest only. AN INTRODUCTION TO BIOLOGY.

Second edition. By J. and A. Churchill. Pp. 580. 25s.

MANY people have the object of physiology is and physics; it is an Prof. Burns shows his study of the working of hold a different faith in so-called science of biology read his book with a command; they will find it and a determined attitude to the whole of human life to the work is the argument is often on account of chlorophyll example, could have and the paragraph on it is partly unintelligible strictly accurate. In growth (pp. 476 ff.) it is Prof. Burns must mean animals," but he does student can discover what only by going via the index of petty difficulties are present and it needs a more pedestrian edition.

MODERN PUBLIC CLEANSING

Its Principles and Problems. M.Inst.M. and C.E., M.R.I.C. tendent to the Motherwell Council. London: The Salvation Army Ltd. 1928. Pp. 261. 10s.

THIS book covers adequately topics germane to the collection of refuse. It is concisely written, presentation from the first chapter to the numerous illustrations, nearly all of which are reproduced. For the convenience appropriate questions are set at chapter, and the last page consists of works consulted. The methods of storage and disposal of refuse are clearly dealt with advantages and disadvantages of each in a very practical manner. Valuable information given regarding land reclamation scheme management, with particular reference to the ford method. The chapter on street cleaning contains a useful discussion of this subject.

Mr. Thompson has produced an excellent reference for all members of the public health and a reliable guide for the student.

autumn of 1927. Again, as in 1927, the cases occurring in the winter and spring and even up to early in July, 1928, were diagnosed as typhoid or paratyphoid fever. In retrospect they are seen to have been typical cases of dengue fever.

The epidemic reached its peak in the second half of August, and from then progressively diminished, but not before nearly every inhabitant of Athens and Piræus had been stricken. The comparatively few who had been infected in the previous autumn escaped with few exceptions. From mid-August the infection was carried by incubating cases to the provinces outside Athens. It raged in the centre and south of Greece; the north was less affected, and in the northern mountains the only cases were refugees from Athens. Altitude by itself, however, is of uncertain protection, for in Syria dengue has occurred at 5000 ft. above sea-level. Clinically the illness presented its typical features—sudden onset, slight rigor, headache, increasingly severe bone and muscle pains, and fever rising to 40° C. In most cases during the first two days there was an intense erythema of face and thorax, becoming scarlatiniform on third and fourth days. At this point the temperature fell, to rise again to a maximum on sixth and seventh, or rarely eighth day, and then dropping sharply with profuse sweatings. In some the exanthem was terminal. Gastro-intestinal disturbances were frequent. In not a few there was slight albuminuria and slight pulmonary congestion. During recovery there was bradycardia. At first the epidemic was benign in character; later it became clinically severe, so that deaths occurred not only in the aged and previously diseased, but a few also in the young and previously healthy. Among these severe cases there occurred hæmoptysis, hæmatemesis, intestinal and uterine hæmorrhages, severe albuminuria and hæmaturia, cerebral hæmorrhage, convulsions, syncope, nervous and psychic troubles. The great majority of fatal cases, however, were among the aged. Relapse appeared only among those who left bed and returned too soon to everyday work, the relapse being in every feature more severe than the primary attack. Autopsies were few. They revealed no inflammatory lesions, but rather a cellular degeneration in liver, kidney, and heart. The stomach and intestines showed submucous petechiæ or larger hæmorrhages. The suprarenals were apparently unaffected. There were certainly many more than 800,000 cases: 1240 deaths were recorded. Treatment was symptomatic. The blood of infected persons showed a leucopenia with relative lymphocytosis; no spirochæte was found. Investigations undertaken by the Pasteur Institute in Athens confirmed the findings of Ashburn and Craig. Filtered and unfiltered blood conveyed the disease by direct transmission to healthy persons. The disease was also experimentally transmitted by *Aedes ægypti* 12 days after their feed on infected persons, and the *aedes* remained infected during their life.

Atmospheric temperature during the summer of 1928 in Athens and generally all over Greece was high. In 1927 and throughout the summer of 1928 an astounding increase in the numbers of *Aedes ægypti* was noted. The untidy sloppiness of most Greek houses and yards provided innumerable and ideal breeding places for *aedes*. It was noted at Salonika in September, 1928, that *aedes* abounded in the small hutments where lived "refugees"—dengue fever smote all these families—and was entirely absent from the households of better dwellings not far off where *aedes* was very scanty. Prevention obviously lies primarily in the destruction of *aedes*. The community that suffers from dengue fever has deserved the visitation.

Annotations.

"Ne quid nimis."

BACILLUS ABORTUS IN MAN.

THE diagnosis of new human diseases is always an interesting process. It needs a particular genius to recognise that things which were thought to be the same are really different, and men like Addison and Bright are few and far between. But ordinary curiosity will often find a thing if it is looking for it, and it seems likely that infection with the organism which causes contagious abortion in cattle may now be definitely added to the list of our endemic human diseases. The evidence is summarised in the papers by Dr. Theodore Thompson and by Dr. H. Harrison and Dr. G. S. Wilson, which will be found in our present issue. It is not finally complete and convincing, for the organism has not been actually isolated from any of the British cases which have been identified by agglutination reactions; but it constitutes a strong case, and a wider ventilation of the possibility should soon lead to the discovery of more and conclusive examples. It is perhaps significant that the new evidence relates to the north-western counties; the disease may be commoner in some parts than others. Clinically it belongs to the large class of disease known to the honest practitioner as G.O.K. The onset is gradual and the general illness often too slight to send the patient to bed, the main symptoms being lassitude, headache, and joint pains with a certain amount of fever, which may be irregular, continuous, or paroxysmal. This goes on for weeks or even months, and there is nothing obviously diagnostic. What is so much needed is that suspicious cases should be investigated in detail and the first thing to do is to test the serum against *Bacillus (Brucella) abortus*. If a positive result is obtained the cultivation of the organism from the blood and urine should be attempted. As Dr. R. A. Kern points out¹ in an admirable article on the clinical aspects, the more the disease has been looked for in the United States the more it has been found, and the same will probably prove true in this country. He also mentions, which we very much regret, that Dr. Alice Evans, to whom so much of our knowledge of the bacteriology is due, has herself caught the infection. We wish her a speedy recovery.

THE HEALTH PROBLEMS OF A SCOTTISH BURGH.

THE translation of Dr. J. Parlange Kinloch in the coming year to the Scottish Board of Health adds a special significance to the report which he has issued as chief health officer of the royal burgh of Aberdeen. Dr. Kinloch tells us that in the course of the year 1927 the parish council and the town council unified the statutory hospital services of the city, and thus took the first step in a great project of hospital reform. The former poor-law hospital, reconditioned as a general hospital of modern type with 220 beds and an orthopædic hospital of 160 beds, was formally opened as "Woodend Hospital" on Oct. 14th, 1927, by Sir John Gilmour, Secretary of State for Scotland. The hospital has been recognised as a complete training school for nurses. Under the new arrangement the town council have taken over all the poor-law medical buildings and have undertaken the treatment of all poor-law patients, thus anticipating the proposed poor-law reforms. An extension of the city fever hospital at a cost of £57,000 is in full progress. The new Royal Hospital for Sick Children is approaching completion, and the success of the Lord Provost's appeal for £100,000 for the provision of a new Royal Infirmary and a new maternity hospital on the same site is assured. Every effort is being made by the town council to coöperate with

X RAY NOMENCLATURE.

THERE are few branches of medicine with a more troublesome vocabulary than radiology. To begin with, the radiologist is by his name a specialist in the use of rays. In practice he specialises in X rays and often also in radium, but not by any means always in rays of ultra-violet or infra-red light. The exponents of these last devices may justly be asked to invent names for themselves, for the X ray man was first on the scene. They have indeed begun to do so, for we remember having seen UVology, which perhaps is intended to be read uviology, and IRology or iriology might follow suit. But how is a specialist in X rays to be distinguished from a specialist in radium? The distinction may seldom arise, but when details of technique are being discussed it may be unavoidable. The French have solved it with precision by using *radiothérapie* alongside *radiumthérapie*. The difficulty then arises that there is no adjective or verb corresponding to "X ray." The X ray photographer probably feels this deficiency more keenly than anyone else. His work makes immense demands on skill and patience, and when his child is triumphantly brought forth he has the humiliation of being uncertain what to call it. The word "radiogram" has been snatched from under his nose and applied to a message transmitted by wireless telegraphy, whilst "radiograph," by analogy with "telegraph," suggests an apparatus rather than its product. If he applies to philological friends for a substitute they produce "skiagram," which drives him, baffled, back on the phrase "X ray photograph"; and after every lecture in which this occurs several times in quick succession he relapses into deeper despair. His difficulty when asked what he is doing to the patient is even worse. He may say he is X raying him or has X rayed him, but he cannot, if he is anything of a purist, write this. Still less can he say he is "X ray photographing" him. "Radiographing" is possible, but it does not seem to be generally accepted, and the exponents of wireless have already almost annexed it for the transmission of pictures. To meet the difficulty the Americans have boldly taken "Roentgen," the distinguished name of the inventor of X rays, and used it as the foundation of their X ray vocabulary. The subcommittee on nomenclature recently appointed by the Section on Radiology of the American Medical Association to standardise the terminology of the science have developed this plan very fully.¹ They restrict the use of "X ray" as an adjective—with a small x—to concrete nouns such as "apparatus," "tube," and presumably also "dermatitis," and recommend "roentgen" when dealing with abstractions. If their report is adopted, it will be necessary to speak of roentgen therapy and roentgen diagnosis; patients will be roentgenographed and their fractures will be illustrated in roentgenograms. Movements will be studied by roentgenoscopy—and presumably the patient will be roentgenoscoped, since the report does not include the handy term "screened." It is fairly certain that most radiologists in this country, rightly or wrongly, would sooner have no roentgenological vocabulary at all than this one. It is scientific and consistent, and the American workers already consider it adequate and admirable. Why, then, should it seem to English eyes so unspeakably hideous? The explanation probably lies in the conditioned reflex which leads the English scientific man—despite neglect of the classics—to expect a Greek or Latin root in his technical terms. When the

proper name looks sufficiently like one, the incongruity passes unnoticed and no one is injured; faradic, milliampères, and galvanometry do not offend the most pedantic eye. It is unfortunate that Teutonic inventors, who are so very prolific, should mostly have names that clash with classical terminations. Even the simplest attempts to combine them, such as "Hertzian" or "Graafian," do not look right after decades of honourable use. The Teutons themselves experience the same difficulty; a terrible example is the phrase, almost an indispensable one, "struma basedowifcata," meaning goitrous tissue which has undergone the changes peculiar to Graves's or Basedow's disease. In the Middle Ages some learned monk would have suggested a Latin cognomen. But there is now no clear way out of the difficulty; there is no equivalent for "roentgenograph," and the English radiologist must simply take it or leave it. In this journal it has for some time been the custom to ignore the competition of wireless, using radiogram for the photograph and radiography for the process which produces it. We do not propose to alter this convenient practice until persuaded that a change is in the public interest; nor until we are convinced that Roentgen is the best way of spelling Röntgen, whose name has just been commemorated in the term Rontgen for the new international unit of X rays. The eponymous society in this country gave a lead some years ago in spelling Rontgen without the umlaut—a lead which we gladly followed and to which we have remained faithful although the Röntgen Society has relapsed. Now that the Society has amalgamated with the British Institute of Radiology we hope they may combine in paying WILHELM CONRAD RÖNTGEN the well-merited compliment of anglicising his name.

DENGUE FEVER.

IN 1927 the town of Durban and its vicinity swarmed with *Aedes aegypti* (*Slegomyia fasciata*). The sanitary sloth thus plainly signalled was justly rewarded during the latter half of 1927 with some 50,000 cases of dengue fever.¹ In the autumn of that year a small epidemic of dengue fever occurred in Athens; and in the summer and autumn of 1928 an epidemic of dengue of unexampled severity, which from Athens swept over nearly the whole of Greece. The main features of this epidemic were described in our issue of Sept. 1st (p. 454) and Dr. Phocion Copanaris's report to the Office International d'Hygiène Publique has now appeared.² Favourable climatic conditions permitted prolongation of life and development of *Aedes aegypti* all through the winter in certain quarters of the city of Athens, in warm houses, and in cess pits which by their construction held a considerably higher temperature than that of the air outside. In these warm shelters *aedes* escaping the lethal action of cold formed the connecting chain between the autumn epidemic of 1927 and the culminating enormous epidemic of the summer of 1928. It has been shown that *aedes* once infected remains infective for so long as she lives. During winter and spring these *aedes* infected a certain number of persons who in turn infected fresh generations of *aedes*. It is noteworthy that the epidemic of 1928 started in the same crowded, ill-ventilated, and insanitary quarter of Athens in which began the epidemic in the

¹ THE LANCET, 1928, i, 256.² Bulletin Mensuel, October, 1928, vol. xx., No. 10.¹ Jour. Amer. Med. Assoc., Sept. 29th, p. 960.

Kelsted and Schiodt suggest that failure to acidify the urine sufficiently is one of the reasons for these comparatively poor results, and they think that some patients may be incapable of secreting a more strongly acid urine because they form too much ammonia. The ammonia formed on cleavage of the hexamine, the decomposition of epithelial cells and leucocytes, and the products of bacterial growth may all tend to counteract urinary acidity. One reason why their results are not as good as those of other workers may, they suggest, be that they allowed plenty of fluids, and they give reasons for thinking that a restricted fluid intake should make acid disinfectant treatment more efficient.

A WARNING TO STRONG SWIMMERS.

Dr. W. A. Young, director of the Medical Research Institute of the Gold Coast, was a particularly expert swimmer, and before his death from yellow fever last May he wrote an article¹ suggesting a possible cause of fatalities in surf-bathing. In not a few autopsies on native bathers found washed up on the beach Dr. Young noted that the lungs were aerated and there was no water in the stomach, but this organ occasionally showed some distension. He was in the habit of returning the cause of death as heart failure from prolonged exertion, but a paper on hypochlorhydria and air-swallowing² suggested to him that the air-swallowing which took place while swimming might cause sufficient distension of the stomach to lead to functional angina pectoris. In order to swim out to sea against large breakers it is necessary to dive deeply, and even on the surface breathing is a matter of picking the right moment and dodging the foam and chop. It is therefore necessary to hold the breath for long periods and to breathe in quick gulps as opportunity offers. While these gulps may themselves cause a certain amount of air-swallowing, Dr. Young thought it more probable that air entered the stomach while the swimmer was under water. After the breath has been held against exertion for a certain length of time, he said, the respiratory centre refuses to be controlled; the expiratory muscles contract slightly, the cheeks puff out a bit, and air is swallowed. On reaching the surface, even though a deep breath be taken at once, he had noticed that there was sometimes a slight feeling of nausea and a curious sensation of lack of confidence. Eructation gave immediate but not complete relief; it had to be repeated several times to restore well-being, and there might be actual vomiting. Both from his own experience and from post-mortem findings Dr. Young believed it likely that this pneumatic distension of the stomach could cause reflex cardiac failure. As he remarked, this bears out the traditional advice "not to bathe on a full stomach"; it is not so much the food that matters as the room it takes up, so that a very little air can cause a lot of distension. If eructation is impossible—and it is a feat of which not everyone is capable—the remedy suggested was to let the air slowly trickle out of the mouth under water when the respiratory strain became too great. This should relieve the intra-buccal pressure and avert the necessity for swallowing.

INTRAVENOUS QUININE.

A report³ on limitations to the use of intravenous quinine in the treatment of malaria has been presented to the Council on Pharmacy and Chemistry, New York, by Dr. Kenneth F. Maxey, of the United States Public Health Service. In the course of an able summary he recalls that J. Morgenroth in 1918 estimated that the quinine content of the blood was 1 in 20,000 a few minutes after intravenous injection, and 1 in 150,000 after oral administration of therapeutic doses. Disappearance of the drug from the

blood is very rapid; R. A. Hatcher and H. Gold could not detect its presence in individual specimens 30 minutes after oral or intramuscular administration. It is not merely excreted, for only 25 per cent. can thus be accounted for, the rest being broken up into simpler substances, a process for which the liver seems to be largely responsible. W. Kirschbaum has produced malarial infection by injecting blood which had been set aside for 24 hours after being mixed with quinine to the extent of 1 in 10,000, a concentration far greater than has ever been maintained in circulating blood. Again, in certain cases which they investigated, W. Ramsden, I. J. Lipkin, and E. Whitley found the quinine content of the blood to be highest, and cinchonism greatest, in those in whom parasites persisted longest. Clearly, then, quinine in itself is not plasmodicidal. But of the effect of quinine in curing malaria there is no question at all, and we must suppose that it exercises its striking action in some indirect way. We have to recognise that intravenous injection does not act by suddenly making available a large amount of parasitocidal substance. And, if the liver is the organ where quinine is not only most rapidly snatched from the circulation but most effectively turned into the plasmodicidal substance—whatever that may be—then intravenous medication does not seem to lead to the desired result as directly as administration via the mouth and portal vein. Accurate observations of the efficiency of intravenous quinine medication are due to British observers headed by J. W. W. Stephens in Liverpool and H. W. Acton in India. The latter have shown that with it the maximum disappearance of plasmodia from the blood occurs within the first 24 hours, whereas with oral administration it takes place in the third 24 hours. But there is no evidence that actual disinfestation is more readily obtained by one method than with the other, while the potential depressant action of intravenous quinine has been amply proved in India by R. McCarrison and J. W. Cornwall and by U. N. Brahmachari. Moreover, if any of the drug spill into the surrounding tissues these will slough, whilst thrombosis, so well established as occurring after its injection into varicose veins, has been reported even in healthy ones. Thus the intravenous route should probably be reserved for cases in which speedy action is essential—e.g., when there are urgent cerebral symptoms or when a swarm of subtertian parasites in the peripheral blood presages their onset—or in which the stomach refuses to retain the drug. The quinine should be introduced slowly, in considerable dilution, and in moderate doses, guarded if necessary with adrenalin; the blood pressure should be closely watched, and administration must be strictly aseptic. Intravenous quinine may in this way with reasonable safety be made available for those few special conditions in which its value has been fully demonstrated.

THE IDEAL ANNUAL HEALTH REPORT?

THE New York State Department of Health publishes every Monday a four-page sheet called *Health News*. Under the heading "Which Kind of an Annual Report is Yours?" a writer in this periodical classifies annual reports as surveys and obituaries. The latter are defined as recitations in a eulogistic, but monotonous, way of the deeds of the past. They serve merely as records which are consulted only if occasion demands. The survey, on the other hand, "not only tells what has been accomplished and how, but compares results, so that those things which are lacking or poorly done are emphasised sharply by contrast." Such a report stimulates to better work in the future. As an example of what such a self-analytical, stock-taking survey ought to be, the annual report of the health officer of White Plains is quoted at some length. He adopted the appraisal form of the American Public Health Association, placing the possible and the actual ratings of the health activities of White Plains side by side. A graph on the title-page showed the percentage of the possible

¹ West African Jour., Oct. 25th, 1928.

² Russell, William; Brit. Med. Jour., 1919, ii., 769.

³ Jour. Amer. Med. Assoc., 1928, xcii., 1372.

the University Medical School and the voluntary hospitals. It is intended that all the statutory hospitals shall be used for teaching purposes, and it is hoped that the professors and heads of departments of the medical school will become ex-officio consultants to the municipal hospitals.

The exact details of the working arrangements between the town council and the medical school and voluntary hospitals have yet to be settled. The town council have now to provide for the parish council infants, and this has been done by the provision of ten additional cots, free from the poor-house environment, at Burnside Home for Mothers and Children. This home now has accommodation for 10 mothers and 42 children, and is mainly utilised for the admission of married women after confinement, with the object of providing them with rest and instruction in baby care. Unmarried mothers are also admitted for their first pregnancy. Another home with accommodation for 8 mothers and 10 infants is mainly used for unmarried mothers both before and after confinement. The marasmus ward in the city hospital provides 22 cots for infants suffering chiefly from nutritional disorders. As another part of the hospital reorganisation scheme arrangements have been made for the admission of post-encephalitics and epileptics as voluntary patients to Kingseat Mental Hospital. In the new hospital scheme the town council is working in full co-operation with the county council and the authorities of the other North-Eastern counties. Dr. Kinloch visualises ultimately a hospital organisation for Scotland on a regional basis grouped mainly around the four medical schools.

The report contains a review of infant mortality, undertaken by Dr. Hilda Menzies, who shows that, whereas in 1856-60 the Aberdeen infant mortality was considerably lower than that of Edinburgh, Dundee, or Glasgow, this superiority was lost in 1886-95, and in 1921-25 the figures were: Edinburgh 91, Glasgow 107, Dundee 113, Aberdeen 115. From her investigation Dr. Menzies finds that the infant mortality from "developmental diseases" during these 70 years has increased by 79 per cent. in Aberdeen, by 3 per cent. in Edinburgh, and by 1 per cent. in Dundee, whilst in Glasgow it has decreased by 9 per cent. The increase appears to be a real one in Aberdeen, and the reason why Aberdeen has lost its early advantage over the other three Scottish towns deserves the closest investigation. It has been suggested by other observers that the introduction of a foreign element has added to the vigour of the stock, and it is noteworthy that Glasgow, the town of the most hybrid stock, has shown the steadiest rate of decrease in infant mortality, whereas Aberdeen, the town of the purest race, has come off worst for infant mortality from "developmental diseases."

ANTERIOR POLIOMYELITIS.

Dr. W. M. Dickie¹ gives many interesting details of the epidemic of anterior poliomyelitis in California in 1927, and of the measures taken against it. The epidemic was at its height in July and August, and of 1270 cases reported, 237 proved fatal. How inadequate is the old name of "infantile paralysis" for the disease is shown by the fact that out of 1385 cases in which the age was recorded, 145 (or over 10 per cent.) of the patients were aged 20 or over. In this epidemic the average age at onset was perhaps unusually high, for nearly 70 per cent. of those affected were 4 years old or more, whilst nearly 40 per cent. were over 9. During the acute illness serum treatment was tried in a small proportion of the cases, but does not seem to have been very useful. A large number of deformities and disabilities inevitably remains in the track of the disease, and the organisation which deals with them largely resembles those existing in many parts of this country. Thirty-

one hospitals throughout the State are open to orthopaedic cases on a charitable or partly charitable basis, nine of them in San Francisco, five in Los Angeles. Ten of those in rural communities are well equipped, but the remaining seven in rural communities are stated to be not adequately equipped for treatment. There are orthopaedic clinics in 13 of the counties of the State. By a recent Act of the legislative assembly of California, called the Crippled Children's Act, children up to the age of 18 years may obtain materials or appliances necessary for treatment at the public expense, but the machinery by which this help is to be obtained seems to be rather too elaborate for efficiency and likely to waste time. The State department concerned is also authorised to receive and administer gifts for the relief of cripples and to arrange through local agencies for diagnostic clinics or conferences. Since the passage of the Act 20 patients have been hospitalised, the average cost being 1000 dollars. High though this cost may seem, it has been only kept down to this level by a special hospital rate of 4 dollars a day and a special operating fee charged to the department by the surgeons concerned. Dr. Dickie thinks that the Crippled Children's Act is not entirely satisfactory. He advocates a plan whereby the State should pay one-third of the cost of treatment, charitable agencies and friends the remainder. He realises, as has been done here and elsewhere, that the long after-treatment of many of these cases cannot be carried on in hospital wards owing to its expense, and is impracticable in most homes. He therefore advocates the provision of convalescent homes.

ACID URINARY DISINFECTANTS.

INFECTIONS of the urinary tract are often treated by administering salts which alter the reaction of the urine and thus discourage bacterial growth. In acid urine hexamethylenetetramine may be given in combination with these salts for the antiseptic effect of the formaldehyde which is liberated from it in an acid medium. The results thus obtained are difficult to assess owing to wide variation in the type of cases treated and differences of dosage. K. Kellsted and E. Schiødt,² of Copenhagen, have attempted to place this acidosis therapy on a more accurate basis by finding the difference in pH of urine before and after treatment, and in their preliminary review quote the work of Rostowski who showed that the addition of acid urine to broth cultures of colon bacilli and staphylococci had an inhibitory effect on growth, this effect being proportional to the acidity. They describe their results of treatment in 28 cases of chronic pyelitis and 42 of chronic cystitis, all of which were thoroughly investigated clinically and bacteriologically, and if necessary by cystoscopy and urethral catheterisation. The hydrogen-ion concentration of the urine was measured at intervals both before and during treatment. To acidify the urine they gave calcium or ammonium chloride in tablet form in doses of from 3 to 8 grammes daily, and in 14 cases of pyelitis and 16 of cystitis these were used alone for periods of from 8 to 35 days. In only one of them, a *B. coli* pyelitis, did the urine become sterile, and this was the one in which the acidity was greatest, reaching pH 4.7. In the next test the acid treatment was given together with urinary disinfectants; the 70 cases were treated for periods ranging from 16 to 120 days, hexamine or salol being given in 1 g. doses, or hexylresorcinol in 0.3 g. doses, three times a day. Acidity of the urine was produced in nearly all the patients, but only in seven was it sufficiently strong to give a prospect of much inhibition of bacterial growth from acidity alone, though all the samples were acid enough for the formaldehyde to be bactericidal. Five out of 28 cases of pyelitis— which were mostly long-standing—recovered completely, and the urine was proved to be sterile. Of the 42 cases of cystitis six developed sterile urine.

¹ Jour. Amer. Med. Assoc., Nov. 10th, p. 1417.

Acta Med. Scand., 1925, lxi., 265.

Kelsted and Schiodt suggest that failure to acidify the urine sufficiently is one of the reasons for these comparatively poor results, and they think that some patients may be incapable of secreting a more strongly acid urine because they form too much ammonia. The ammonia formed on cleavage of the hexamine, the decomposition of epithelial cells and leucocytes, and the products of bacterial growth may all tend to counteract urinary acidity. One reason why their results are not as good as those of other workers may, they suggest, be that they allowed plenty of fluids, and they give reasons for thinking that a restricted fluid intake should make acid disinfectant treatment more efficient.

A WARNING TO STRONG SWIMMERS.

Dr. W. A. Young, director of the Medical Research Institute of the Gold Coast, was a particularly expert swimmer, and before his death from yellow fever last May he wrote an article¹ suggesting a possible cause of fatalities in surf-bathing. In not a few autopsies on native bathers found washed up on the beach Dr. Young noted that the lungs were aerated and there was no water in the stomach, but this organ occasionally showed some distension. He was in the habit of returning the cause of death as heart failure from prolonged exertion, but a paper on hypochlorhydria and air-swallowing² suggested to him that the air-swallowing which took place while swimming might cause sufficient distension of the stomach to lead to functional angina pectoris. In order to swim out to sea against large breakers it is necessary to dive deeply, and even on the surface breathing is a matter of picking the right moment and dodging the foam and chop. It is therefore necessary to hold the breath for long periods and to breathe in quick gulps as opportunity offers. While these gulps may themselves cause a certain amount of air-swallowing, Dr. Young thought it more probable that air entered the stomach while the swimmer was under water. After the breath has been held against exertion for a certain length of time, he said, the respiratory centre refuses to be controlled; the expiratory muscles contract slightly, the cheeks puff out a bit, and air is swallowed. On reaching the surface, even though a deep breath be taken at once, he had noticed that there was sometimes a slight feeling of nausea and a curious sensation of lack of confidence. Eructation gave immediate but not complete relief; it had to be repeated several times to restore well-being, and there might be actual vomiting. Both from his own experience and from post-mortem findings Dr. Young believed it likely that this pneumatic distension of the stomach could cause reflex cardiac failure. As he remarked, this bears out the traditional advice "not to bathe on a full stomach"; it is not so much the food that matters as the room it takes up, so that a very little air can cause a lot of distension. If eructation is impossible—and it is a feat of which not everyone is capable—the remedy suggested was to let the air slowly trickle out of the mouth under water when the respiratory strain became too great. This should relieve the intra-buccal pressure and avert the necessity for swallowing.

INTRAVENOUS QUININE.

A REPORT³ on limitations to the use of intravenous quinine in the treatment of malaria has been presented to the Council on Pharmacy and Chemistry, New York, by Dr. Kenneth F. Maxey, of the United States Public Health Service. In the course of an able summary he recalls that J. Morgenroth in 1918 estimated that the quinine content of the blood was 1 in 20,000 a few minutes after intravenous injection, and 1 in 150,000 after oral administration of therapeutic doses. Disappearance of the drug from the

blood is very rapid; R. A. Hatcher and H. Gold could not detect its presence in individual specimens 30 minutes after oral or intramuscular administration. It is not merely excreted, for only 25 per cent. can thus be accounted for, the rest being broken up into simpler substances, a process for which the liver seems to be largely responsible. W. Kirschbaum has produced malarial infection by injecting blood which had been set aside for 24 hours after being mixed with quinine to the extent of 1 in 10,000, a concentration far greater than has ever been maintained in circulating blood. Again, in certain cases which they investigated, W. Ramsden, I. J. Lipkin, and E. Whitley found the quinine content of the blood to be highest, and cinchonism greatest, in those in whom parasites persisted longest. Clearly, then, quinine in itself is not plasmodicidal. But of the effect of quinine in curing malaria there is no question at all, and we must suppose that it exercises its striking action in some indirect way. We have to recognise that intravenous injection does not act by suddenly making available a large amount of parasitocidal substance. And, if the liver is the organ where quinine is not only most rapidly snatched from the circulation but most effectively turned into the plasmodicidal substance—whatever that may be—then intravenous medication does not seem to lead to the desired result as directly as administration via the mouth and portal vein. Accurate observations of the efficiency of intravenous quinine medication are due to British observers headed by J. W. W. Stephens in Liverpool and H. W. Acton in India. The latter have shown that with it the maximum disappearance of plasmodia from the blood occurs within the first 24 hours, whereas with oral administration it takes place in the third 24 hours. But there is no evidence that actual disinfestation is more readily obtained by one method than with the other, while the potential depressant action of intravenous quinine has been amply proved in India by R. McCarrison and J. W. Cornwall and by U. N. Brahmachari. Moreover, if any of the drug spill into the surrounding tissues these will slough, whilst thrombosis, so well established as occurring after its injection into varicose veins, has been reported even in healthy ones. Thus the intravenous route should probably be reserved for cases in which speedy action is essential—e.g., when there are urgent cerebral symptoms or when a swarm of subtertian parasites in the peripheral blood presages their onset—or in which the stomach refuses to retain the drug. The quinine should be introduced slowly, in considerable dilution, and in moderate doses, guarded if necessary with adrenalin; the blood pressure should be closely watched, and administration must be strictly aseptic. Intravenous quinine may in this way with reasonable safety be made available for those few special conditions in which its value has been fully demonstrated.

THE IDEAL ANNUAL HEALTH REPORT?

THE New York State Department of Health publishes every Monday a four-page sheet called *Health News*. Under the heading "Which Kind of an Annual Report is Yours?" a writer in this periodical classifies annual reports as surveys and obituaries. The latter are defined as recitations in a eulogistic, but monotonous, way of the deeds of the past. They serve merely as records which are consulted only if occasion demands. The survey, on the other hand, "not only tells what has been accomplished and how, but compares results, so that those things which are lacking or poorly done are emphasised sharply by contrast." Such a report stimulates to better work in the future. As an example of what such a self-analytical, stock-taking survey ought to be, the annual report of the health officer of White Plains is quoted at some length. He adopted the appraisal form of the American Public Health Association, placing the possible and the actual ratings of the health activities of White Plains side by side. A on the title-page showed the percentage of the

¹ West African Jour., Oct. 28th, 1928.

³ Jour. Amer. Med. Assoc., 1928, xcii., 1372.

optimum score attained by White Plains, and how 1927 compared with 1926. In the case of tuberculosis control, for example, 68 points were scored out of a possible 100. The score was "perfect" on recording, on nurses' visits to cases, on follow-up of post-sanatorium cases, and on days of hospitalisation, but the clinic patients evidently did not present themselves to the clinic as promptly as they should since too few cases were discovered in the incipient stage, and there was wholly inadequate provision for open-air class-rooms, preventoria, and day camps. Popular health instruction in White Plains was shown at a glance to be much below standard, only nine out of a possible 20 points being scored in this field. Points were lost because no health bulletin was published, no use was made of motion pictures on health, and public lectures on health were but half as numerous as they should be, according to the standard set up by the American Public Health Association. On the other hand, the maximal number of points was scored as far as educational health pamphlets and newspaper publicity were concerned. Medical officers of health with a due sense of decorum and a conviction that public health is a matter within the competence of none but themselves, may perhaps find such methods as those just described more suited to a stock-taking grocer than a scientist. But there is much to be said for the medical officer of health who is willing to submit to the fierce light of publicity—to go back, as it were, to school, there to have his work examined and allotted so many marks, good or bad. The question is, do such methods promote efficiency?

THE DANGEROUS JUNKER.

FATALITIES have sometimes been caused by the pumping of liquid chloroform, instead of vapour, out of a Junker's apparatus into an unconscious patient. This is an accident in anæsthetic administration which should no longer be possible. At an inquest on a patient who died from this cause the hospital authorities are said to have stated recently that "if the apparatus could be improved in any way or better apparatus could be found" they would adopt the safe instrument. It should be known to all institutions and anæsthetists that there are several forms of Junker apparatus which are practically foolproof. For the convenience of our readers these are described and illustrated on p. 1359. Much more important, however, than the form of apparatus, is it for every administrator of anæsthetics to abide by the golden rule—never to use an apparatus without first trying it. This is the only safe way with machines, and now that machinery has invaded so largely the technique of administration of anæsthetics it is an unforgivable fault to take machinery for granted. Machines are good servants, but bad masters. If the administrator leaves safety to the apparatus, he is putting the machine in the place that should be occupied by his own skill, care, and intelligence. There has been produced, we understand, a sort of Robot anæsthetist. We can imagine no more perilous invention. The safety of those to whom a poison is being administered for any purpose must depend on the instructed care of the individual responsible for the dose. If he cannot understand, foresee, and correct the vagaries of unconscious patients' behaviour, disaster may occur. Machinery requires not less but more skill on the part of the anæsthetist than simpler methods. His first duty must always be to test his apparatus.

The coroner's jury at the inquest referred to above returned a verdict of death by misadventure and exonerated the anæsthetist, and a favourable finding by a coroner's jury is reasonably conclusive. It is, however, inevitable that, if further accidents of this kind occur, public opinion will be strongly aroused. When the country realises that the use of one type of apparatus does, while the use of other types does not, involve an actual danger to life, there will be a vigorous demand for the banning of the dangerous type and a vigorous condemnation of those who run

a needless risk. For the miner in the coal-mine Parliament has ordained that only certain approved patterns of safety lamp shall be used. Popular feeling, nowadays easily stirred, might insist that the processes of departmental inspection and approval should be applied also to the preliminaries of surgical operation. Meanwhile voluntary action can forestall the requirement of statutory compulsion. Hospitals and anæsthetists would do well forthwith to discard apparatus which contains the possibility of a mistake involving appalling consequences and adopt a type which does not offer this opportunity to human fallibility.

THE GRANULES OF THE TUBERCLE BACILLUS.

SINCE the time of Koch every worker in the field of bacteriology has been conversant with the fine darkly-stained violet granules which are found in the tubercle bacillus when treated by the Ziehl-Neelsen method. To these Carl Spengler added his "splitter" bodies, and in more recent times Hans Much described the various forms of granular dust which are known by his name. In a series of photomicrographs taken with a 1/18th-inch immersion lens, Dr. W. C. Minchin¹ claims that he can detect in tubercle cultures the phenomena of division, budding, and protrusion of tubes, from which can be deduced a definite life-cycle. The pictures are suggestive, although it is generally agreed that morphology, unsupported by other evidence, offers pitfalls to the unwary. Dr. H. C. Sweany,² of Chicago, has endeavoured to carry the subject a step further by a careful study of the life-history of the tubercle bacillus. He describes various types of granules, with illustrative drawings both in line and water-colour. But all this work has brought us little nearer than Koch was to the solution of the question: What are these granules? It is essential that any theory should have cogent reasons for its proposition. Dr. Sweany gets down to basic principles. If these granules are part of the life-cycle of the tubercle bacillus they follow presumably the biological laws which govern bacterial life. One of the characteristics which makes it impossible at present to reconcile the granules with any ordinary life-cycle is the random nature of the changes. At one time the appearances suggest atavistic change, at another the remnant of a regular cycle. Time was when all these changes were considered to be valuable in diagnosis and prognosis—a point on which Dr. Minchin still lays stress. For the moment this aspect seems to us less important than is the possible relationship of the granules to the suggested transformation of paratubercle bacilli into true tubercle bacilli and to the so-called filter-passing virus. Both these points have been raised by the work of continental writers. Before accepting their conclusions it must be certain that they are dealing with comparable material. It is only necessary to hand out to a class the same specimen of tuberculous pus in order to realise how variable may be the morphological appearances presented in the microscopic field. The personal factor of the worker is of no small importance. Meanwhile it is possible that a more vigorous pursuit of the other acid-fast bacilli in nature may yield valuable information.

THE CAUSATION OF LICHEN PLANUS.

THE ætiology of lichen planus has exercised the minds of dermatologists since the days of Hebra, and many and various have been the suggestions made. Dr. S. Neumark,³ after a careful summary of the literature, supports the most recent, and yet by no means novel, view that the eruption is the direct or indirect result of shock—psychical or toxic—on

¹ A Study in Tubercle Virus. By W. C. Minchin. London: Baillière, Tindall and Cox. 1927. Pp. 110. 25s.

² Amer. Rev. Tub., 1925, xvii, 52.

³ Dermat. Woch., 1925, lxxvii, 1666.

the nervous system. The present theory expands and improves on an older one by specifying the sympathetic or vegetative neurons and their connections as the actual neurological paths in the mechanism by which lichen planus is produced. The evidence in favour of this hypothesis is drawn mostly from the literature, but we are reminded that severe emotional states are often the prelude to an attack, that highly strung and unstable persons are the most frequent victims, and that general shock is always associated with disturbance of the sympathetic system. On the more narrow dermatological side it may be noted that lichen planus is very often a pigmentary affection, that it sometimes occurs with vitiligo, and that in more than one case it has followed administration of thallium acetate. Some support for the theory is also forthcoming on the therapeutic side. Lumbar puncture, as is well known, may have a curative effect in the acute generalised case, and, according to Margarot, it exercises a powerful stimulus on the parasympathetic as evidenced by immediate slowing of the pulse and a fall in blood pressure. Ignoring the effects of neosalvarsan—well recognised as disturbing the sympathetic nervous system—both in the production and control of lichenoid eruptions, we are next invited to consider the effects of radiotherapy administered in the interscapular and lumbar regions. This often has excellent results in severe cases of lichen planus, though sometimes it may seriously aggravate the condition. Neumark thinks it may be assumed with fair certainty that the results so obtained are dependent on the direct action of the rays on the sympathetic ganglia at the sides of the vertebral column, and the subsequent hyperidrosis, localised to these areas, is suggestive of such a specific action. He concludes his interesting deductions with a report of investigations he undertook with the object of supporting the thesis from the biochemical point of view. In ten cases of the disease treated with X rays it was found that the blood-sugar of the fasting patient after having been somewhat raised fell quite definitely after the case had been cured or alleviated by the treatment. A similar investigation of the cholesterin and uric acid content of the blood gave similar results. It is admitted that the number of cases so investigated is too small for any conclusions, but so far as this evidence goes it further supports the view that in lichen planus we have an example of sympathetic reaction comparable to that which is regarded as responsible for the initiation of herpes zoster.

DURING 1928 the Royal Medical Benevolent Fund has made 457 grants amounting to £8621. This sum is £1456 in excess of that for the year 1927. Annuities totalling £4970 have been given to 185 persons, the average amount of these annuities being £10 per annum. Owing to a recent legacy, however, the Fund has been able to grant six annuities of £100 each. An increase of £1456 on the grant account is very heavy and necessitates an urgent appeal that subscriptions and donations in 1929 will not only be maintained but very greatly increased, so that the Fund may extend its work as well as continue to help those already on its books. Contributions should be sent to the Hon. Treasurer at 11, Chandos-street, Cavendish-square, London, W. 1.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Dec. 19th the degree of Doctor of Science was conferred on Dr. Major Greenwood, F.R.S., professor of epidemiology and vital statistics in the University, for a thesis on the Laws of Mortality from a Biological Point of View.

It was reported that the Rhodes Trustees have given £5000 for the fund being raised to build a Hall of Residence for Overseas and British Students and that they had provisionally decided to set aside a similar sum towards the building of a Students' Union on the Bloomsbury site.

XVI.

THE CHEMICAL EXAMINATION OF FÆCES.

BY J. H. RYFFEL, B.Sc. LOND., B.CHIR. CAMB.,
CLINICAL CHEMIST, GUY'S HOSPITAL.

THE chemical examinations of fæces that can be usefully employed are not many, but may be of great importance in suitable cases. Unless a determination of fat is required, the specimen tubes 2½ inches long usually employed are sufficient, and there are no special precautions to be employed in the collection of a specimen except where dieting is necessary (see below).

Blood.

The value of looking for blood in fæces is not universally accepted. If it is to yield useful results, unless the amount of blood is large enough to give the spectrum of acid hæmatin on extraction, it is quite essential to diet the patient for four days preliminary to examination. No device for diminishing the sensitiveness of the tests will exclude the effect of diet, unless the sensitiveness is so reduced as not to give reliable results. The diet given must be free from hæmoglobin and from chlorophyll—i.e., it must not include meat, fish, or meat extracts, green vegetables or coloured fruits. Potatoes, eggs, and vegetable substitutes for meat extracts are allowable. A useful device is to give a dose of charcoal when starting the diet, and to wait until the charcoal has disappeared from the fæces before the specimen is collected. A criticism often made is that there is no indication from which part of the intestinal canal the blood comes from. This is not absolutely true, since, for example, blood from hæmorrhoids will not show hæmatoporphyrin, but there is certainly no essential difference detectable between the results of bleeding from the colon and from the stomach, and bleeding from the mouth or gums has to be rigidly excluded as a possible source of error. The most valuable examination consists in extracting the fæces with glacial acetic acid and ether, water being added to cause the ether to separate. Part of the ethereal extract can then be used for the benzidine or the guaiac test. The remainder is mixed with diluted hydrochloric acid and allowed to separate, which it does immediately. The spectra of acid hæmatin and of chlorophyll can then be recognised in the upper or ether layer, while acid hæmatoporphyrin is seen in the watery layer. Stercobilin is found in both layers. Chlorophyll is mainly useful in that it shows that dieting has been inadequate. A visible spectrum of acid hæmatin signifies the presence of a large amount of blood. When this is not visible, a positive guaiac or benzidine test signifies the presence of acid hæmatin in quantity insufficient to show a spectrum.

Hæmatoporphyrin does not give the guaiac or the benzidine test. Its presence, detectable in a spectrum, shows that the blood has undergone change. To what extent this change takes place depends on the source of blood, on the individual, and on the substances in the gut at the time. Examination of the spectrum is complementary to the guaiac test. Some cases are met with who show hæmatoporphyrin only, although definite bleeding is known to occur; on the other hand, if much bismuth and other carbonates are given in the course of the treatment of gastric or duodenal ulcer, the fæces frequently show a positive guaiac test and no hæmatoporphyrin. Hæmatoporphyrin may conceivably occur apart from bleeding; this has been observed in some cases of

optimum score attained by White Plains, and how 1927 compared with 1926. In the case of tuberculosis control, for example, 68 points were scored out of a possible 100. The score was "perfect" on recording, on nurses' visits to cases, on follow-up of post-sanatorium cases, and on days of hospitalisation, but the clinic patients evidently did not present themselves to the clinic as promptly as they should since too few cases were discovered in the incipient stage, and there was wholly inadequate provision for open-air class-rooms, preventoria, and day camps. Popular health instruction in White Plains was shown at a glance to be much below standard, only nine out of a possible 20 points being scored in this field. Points were lost because no health bulletin was published, no use was made of motion pictures on health, and public lectures on health were but half as numerous as they should be, according to the standard set up by the American Public Health Association. On the other hand, the maximal number of points was scored as far as educational health pamphlets and newspaper publicity were concerned. Medical officers of health with a due sense of decorum and a conviction that public health is a matter within the competence of none but themselves, may perhaps find such methods as those just described more suited to a stock-taking grocer than a scientist. But there is much to be said for the medical officer of health who is willing to submit to the fierce light of publicity—to go back, as it were, to school, there to have his work examined and allotted so many marks, good or bad. The question is, do such methods promote efficiency?

THE DANGEROUS JUNKER.

FATALITIES have sometimes been caused by the pumping of liquid chloroform, instead of vapour, out of a Junker's apparatus into an unconscious patient. This is an accident in anæsthetic administration which should no longer be possible. At an inquest on a patient who died from this cause the hospital authorities are said to have stated recently that "if the apparatus could be improved in any way or better apparatus could be found" they would adopt the safe instrument. It should be known to all institutions and anæsthetists that there are several forms of Junker apparatus which are practically foolproof. For the convenience of our readers these are described and illustrated on p. 1359. Much more important, however, than the form of apparatus, is it for every administrator of anæsthetics to abide by the golden rule—never to use an apparatus without first trying it. This is the only safe way with machines, and now that machinery has invaded so largely the technique of administration of anæsthetics it is an unforgivable fault to take machinery for granted. Machines are good servants, but bad masters. If the administrator leaves safety to the apparatus, he is putting the machine in the place that should be occupied by his own skill, care, and intelligence. There has been produced, we understand, a sort of Robot anæsthetist. We can imagine no more perilous invention. The safety of those to whom a poison is being administered for any purpose must depend on the instructed care of the individual responsible for the dose. If he cannot understand, foresee, and correct the vagaries of unconscious patients' behaviour, disaster may occur. Machinery requires not less but more skill on the part of the anæsthetist than simpler methods. His first duty must always be to test his apparatus.

The coroner's jury at the inquest referred to above returned a verdict of death by misadventure and exonerated the anæsthetist, and a favourable finding by a coroner's jury is reasonably conclusive. It is, however, inevitable that, if further accidents of this kind occur, public opinion will be strongly aroused. When the country realises that the use of one type of apparatus does, while the use of other types does not, involve an actual danger to life, there will be a vigorous demand for the banning of the dangerous type and a vigorous condemnation of those who run

a needless risk. For the miner in the coal-mine Parliament has ordained that only certain approved patterns of safety lamp shall be used. Popular feeling, nowadays easily stirred, might insist that the processes of departmental inspection and approval should be applied also to the preliminaries of surgical operation. Meanwhile voluntary action can forestall the requirement of statutory compulsion. Hospitals and anæsthetists would do well forthwith to discard apparatus which contains the possibility of a mistake involving appalling consequences and adopt a type which does not offer this opportunity to human fallibility.

THE GRANULES OF THE TUBERCLE BACILLUS.

SINCE the time of Koch every worker in the field of bacteriology has been conversant with the fine darkly-stained violet granules which are found in the tubercle bacillus when treated by the Ziehl-Neelsen method. To these Carl Spengler added his "splitter" bodies, and in more recent times Hans Much described the various forms of granular dust which are known by his name. In a series of photomicrographs taken with a 1/18th-inch immersion lens, Dr. W. C. Minchin¹ claims that he can detect in tubercle cultures the phenomena of division, budding, and protrusion of tubes, from which can be deduced a definite life-cycle. The pictures are suggestive, although it is generally agreed that morphology, unsupported by other evidence, offers pitfalls to the unwary. Dr. H. C. Sweany,² of Chicago, has endeavoured to carry the subject a step further by a careful study of the life-history of the tubercle bacillus. He describes various types of granules, with illustrative drawings both in line and water-colour. But all this work has brought us little nearer than Koch was to the solution of the question: What are these granules? It is essential that any theory should have cogent reasons for its proposition. Dr. Sweany gets down to basic principles. If these granules are part of the life-cycle of the tubercle bacillus they follow presumably the biological laws which govern bacterial life. One of the characteristics which makes it impossible at present to reconcile the granules with any ordinary life-cycle is the random nature of the changes. At one time the appearances suggest atavistic change, at another the remnant of a regular cycle. Time was when all these changes were considered to be valuable in diagnosis and prognosis—a point on which Dr. Minchin still lays stress. For the moment this aspect seems to us less important than is the possible relationship of the granules to the suggested transformation of paratubercle bacilli into true tubercle bacilli and to the so-called filter-passing virus. Both these points have been raised by the work of continental writers. Before accepting their conclusions it must be certain that they are dealing with comparable material. It is only necessary to hand out to a class the same specimen of tuberculous pus in order to realise how variable may be the morphological appearances presented in the microscopic field. The personal factor of the worker is of no small importance. Meanwhile it is possible that a more vigorous pursuit of the other acid-fast bacilli in nature may yield valuable information.

THE CAUSATION OF LICHEN PLANUS.

THE ætiology of lichen planus has exercised the minds of dermatologists since the days of Hebra, and many and various have been the suggestions made. Dr. S. Neumark,³ after a careful summary of the literature, supports the most recent, and yet by no means novel, view that the eruption is the direct or indirect result of shock—psychical or toxic—en-

KING EDWARD'S FUND FOR LONDON.

ON Dec. 14th a meeting of the President and General Council of King Edward's Hospital Fund for London was held at St. James's Palace for the purpose of awarding grants to the hospitals and convalescent homes for the present year. The Lord Chancellor, Lord Hailsham, presided and read the following

Letter from the Prince of Wales.

Although I am back in England, I cannot just at present undertake any public engagements. I should be grateful, therefore, if you and Mr. Whitley and the Governor of the Bank of England would continue to act as President's Powers Committee until the end of the year, and I would ask you to tell the council how sorry I am not to be able to take the chair at the distribution meeting on Dec. 14th. I congratulate King Edward's Hospital Fund on the achievements of a year which has seen the completion of the Wells Legacies distribution, the issue of the Pay Beds report, the actual start of the contributory pensions scheme for nurses and hospital officers, the receipt of Sir Otto Beit's magnificent gift for the purchase of radium, and the attainment for the first time of an ordinary distribution of a quarter of a million. I approve the proposal to appoint a special committee to consider the position of the voluntary hospitals under the Local Government Bill, and I wish the King's Fund and the hospitals all possible prosperity in the coming year.

Lord Hailsham then moved from the chair:—

"The General Council of King Edward's Hospital Fund for London desire to express their profound sympathy with His Majesty the King, Patron and Past President of the Fund, in his illness, and their heartfelt wishes for a speedy and complete recovery. They desire also to convey with their humble obedient duty to Her Majesty the Queen, His Royal Highness the Prince of Wales, President of the Fund, and the other members of the Royal Family an expression of sympathy in their prolonged anxiety."

The resolution was seconded by the Rt. Hon. J. H. Whitley and carried unanimously.

The Position of the Fund.

Continuing, Lord Hailsham, after referring to the gift of £50,000 from Sir Otto Beit for the purchase of radium, said the annual distribution this year constituted in itself a great landmark in the history of the Fund, for it was the first time that the ordinary annual distribution had reached the total of a quarter of a million. In order merely to maintain the £250,000 the Fund had to receive during the year at least £90,000. This year's success had been largely due to some special donations: notably two of £10,000 each from two anonymous donors, one of whom had now helped them with gifts of varying amounts for six years running. This did not include Mr. J. J. Crosfield's gift of £10,000 to capital. The Fund had also received an exceptional amount in legacies during the year. Besides the £250,000 in ordinary grants to maintenance and building the list contained the first instalments of the special grants promised in aid of the contributory pension scheme for nurses and hospital officers. This scheme, which the Fund initiated, had now been adopted by 93 hospitals in London and by 58 hospitals in other parts of the country, making 151 in all with a total of nearly 21,000 beds, which was practically one-third of all the voluntary hospital beds in Great Britain and Northern Ireland. If these special grants were included, and also the final grants made last May out of the Wells legacies, the grand total distributed during this year would be no less than £290,000. The publication in July of the report of the Pay Beds Committee had been one of the principal items in the Fund's work. The transfer to the county councils of the infirmaries hitherto carried on under the poor-law would produce great changes in the hospital service, and it was hoped that great improvements would result. But it would be

necessary to work out a scheme by which the voluntary hospitals should continue to make their special contribution to that hospital service, which depended on the fact that both their management and their finance were voluntary. If the voluntary hospitals were not preserved, not only would huge additional sums have to come out of the rates, but the present spirit of the voluntary hospitals, which influenced all other hospitals in this country, would be lost and the whole system would become official. This was the last thing that was desired.

Hon. Treasurer's Statement.

Lord Revelstoke (hon. treasurer) said that last year the estimates enabled the Management Committee to recommend a distribution of £245,000. The League of Mercy contributed an additional £2000, thereby increasing the total to £247,000. In addition to the donation of £10,000 from Mr. J. J. Crosfield, receipts on capital account included a legacy of £3709 from Miss E. A. Marshall, and further sums of £2671 and £1500 from the estates of Sir Julius Wernher and Mr. Samuel Lewis, these two sums being additional to the very large amounts already received from these sources. Miss Marshall's legacy, in accordance with the provisions of her will, would be added to the "family fund" entitled the "Marshall Fund." This fund was established by her brother, Mr. H. W. Marshall, who inaugurated it by a gift of £10,000 $\frac{3}{4}$ per cent. Conversion Stock last year, on the occasion of the luncheon at the Mansion House held to commemorate the thirtieth anniversary of the King's Fund. This was the first "family fund" to appear in the annual report, and it now amounted to £11,334, the whole of this sum being represented by permanent investments. It was interesting to note that, had it not been for the interest on the late Lord Iveagh's bequest of £60,000 received in 1927, the estimates in November, which computed legacies on the basis of the five years' average, would not have reached the £250,000, but would barely have exceeded last year's total of £247,000.

The League of Mercy.

Lord Marshall, in making the annual statement on behalf of the League of Mercy, announced that this year it was proposed to allocate £17,000 to the King's Fund. This was the same amount as the grant of last year, which was £2000 higher than that of the year before. Its grants this year to extra-metropolitan hospitals amounted to £8210. From the inauguration of the League in 1899 it had transferred to the King's Fund from its collections for hospitals a total of £432,034, and had made grants to hospitals outside London totalling £108,907, making a grand total of £540,941.

Grants to Hospitals and Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the Committee on the Distribution to Hospitals (including recovery and convalescent branches), which stated that the amount placed at the disposal of the Distribution Committee for allocation amongst hospitals and their recovery and convalescent branches at the present distribution was £248,000, as against £245,000 last year. The number of hospitals applying for grants was 141, the same number as in 1927—Ormond Maternity Home having dropped out of the list and an application having been received from Wembley Hospital, opened in June last. The Committee were pleased to see, from the King's Fund Statistical Report, that the steady progress of the hospitals was resumed in 1927 after a slight interruption in 1926, the first since 1922. Each of the main sources of revenue—voluntary gifts, receipts on account of services rendered, income from investments and legacies—showed an increase. The combined result, for all the participating hospitals taken together, was a small excess of income over expenditure, although there were still 56 hospitals with deficits for the year, some of them serious. The increase in the grants

hæmatoporphyrinæmia. Hæmatoporphyrin is also found in meconium, but generally speaking hæmatoporphyrin in fæces in recognisable quantity signifies bleeding and nothing else. The significance of the results in various conditions demands some comment. In acute ulcerative colitis red cells are seen and the spectrum of acid hæmatin alone obtained, but when there is less diarrhoea in a milder case the blood is often completely laked and hæmatoporphyrin appears. Malignant growths anywhere in the alimentary canal show hæmatoporphyrin, often with a visible spectrum of acid hæmatin, with a tendency for the hæmatoporphyrin to be more marked the higher the situation of the growth. Provided there is some ulceration the bleeding from growths is both characteristic and persistent. Blood from other sources than growths shows the same relationships with the proviso that, where the amount of blood is large, acid hæmatin is the more conspicuous.

To illustrate the changes that occur we may take the case of hæmatemesis from a gastric ulcer. This is rapidly followed by melæna, a large amount of acid hæmatin being shown by the fæcal extract. As the bleeding gets less the hæmatin diminishes and hæmatoporphyrin increases. Finally, when bleeding ceases completely, hæmatoporphyrin is the last abnormality to disappear.

Ulcers of the body of the stomach are remarkably variable in their bleeding. Thus with a well-marked ulcer there may be no bleeding on one occasion followed shortly afterwards by melæna. Ulcers near the pylorus bleed more consistently, especially if there is any pyloric obstruction. Duodenal ulcers are also variable, but rather in the sense that some types of duodenal ulcer with definite pain do not bleed, or scarcely so, while others, even with little pain, bleed persistently. In this type of ulcer during treatment blood may still be found in the fæces long after all other symptoms have disappeared.

Bile.

Stercobilin can be recognised by its absorption spectrum after extraction. If it is completely, or nearly completely, absent, complete biliary obstruction can be diagnosed. Stercobilin may be practically absent for a short period in catarrhal jaundice, but generally in this disease some stercobilin is present. This is notably so in spirochaetal jaundice, where stercobilin is not appreciably diminished. Fatty stools are lightly coloured, not only owing to the admixture of fatty bodies, but the stercobilin is often small in amount irrespective of biliary obstruction. The reason for this is not obvious. Where there is diarrhoea the transformation of bile pigment to stercobilin may be incomplete, so that bile pigment is found as well as stercobilin. In infants the principal pigment is bile pigment, not stercobilin, the change to the latter pigment being only gradually established during the first year of life.

Fatty Substances.

In biliary deficiency the fats in the food are split to fatty acids and glycerine, but the fatty acids are not absorbed. They appear in the fæces mainly as soaps, crystals of which can be recognised under the microscope. The reaction of the fæces is not usually acid. Where there is failure to split the fats, fatty globules can be recognised microscopically, and the reaction of the fæces is often acid. Causes of such failure are pancreatic deficiency and gastro-colic or jejuno-colic fistula. It is of the utmost importance in such cases to eliminate the possibility of the presence of liquid paraffin, as this will appear as fatty globules and also vitiate determinations of neutral fat. In sprue, in coeliac disease, and in obstruction of the lymphatics of the mesentery the fat of the food is split but not absorbed, and appears as soaps usually recognisable in crystalline form. Infants are especially liable to failure in absorption of fat. The stools are acid and fat globules are easily recognised. This condition is often temporary and may be easily dealt with by dieting.

Determinations of Fat and Fatty Acids.—The total fat and fatty acid in the fæces is determined by

extraction in a Soxhlet apparatus after the fæces have been mixed with 1 per cent. hydrochloric acid in alcohol and evaporated to dryness. The extract obtained is then filtered, evaporated, and weighed. It includes some pigment, cholesterol, &c., but these are small in weight and are neglected. If the process is repeated without the addition of hydrochloric acid, the difference between the two results expressed as percentages gives the amount of fatty acid present as soaps. Finally, if the second extract be dissolved in alcohol and ether and titrated with alcoholic potash using phenolphthalein as indicator, a figure is obtained which represents the free fatty acids. Multiplying the number of c.c.m. of N/10 potash used by 0.0284 gives the fatty acid present expressed as stearic acid. If this figure is subtracted from the weight of the second extract the difference represents what is called the neutral fat, which, however, includes cholesterol, and also paraffin, if present. A more correct method would be to digest the neutralised second extract with alcoholic potash until the neutral fat was hydrolysed, and then to titrate with acid to neutrality to determine how much potash had been neutralised by the liberated acid. Cammidge employs Schmidt-Werner milk tubes for extraction instead of the Soxhlet apparatus, thereby saving a considerable amount of time. In the dry fæces the normal figures are:—

	Per cent.
Total fat and fatty acid	15 to 25
Neutral fat	1 to 2
Free fatty acid	9 to 13
Fatty acids as soaps	10 to 15

U.F.A. = Unsoaped fatty acids, 10 to 15 per cent.

The fatty acids as soaps and the free fatty acids plus neutral fat are normally about equal, while the free fatty acid is about nine times as much as the neutral fat. If these determinations are done on the fæces of a case with deficient fat absorption these ratios are disturbed. Thus where there is pancreatic deficiency the neutral fat may be as high as 15 per cent. and equal in amount to the free fatty acid. Biliary deficiency alone gives high soaps and high free fatty acids without appreciably increasing the neutral fat, while pancreatic deficiency (or gastro-colic fistula) is shown by a relatively high neutral fat, the free fatty acid figure being also high in relation to the soaps, as the stools are generally acid in these conditions.

Meat Fibres.

Remnants of muscle fibres are normally seen when meat or fish is taken in sufficient quantity. When the fibres are more numerous, larger and show cross striation, there is some failure in digestion, probably due to lack of trypsin, which often accompanies failure in fat digestion. The excess of unabsorbed fat may also impede digestion of meat. Occasionally over use of liquid paraffin results in excess of meat fibres in the stools, and sometimes meat fibres are found in excess in diarrhoea as a result of intestinal hurry.

Starch.

In a well-marked case of failure to absorb starch the fæces are acid in reaction, and starch grains, especially those in vegetable cells such as those of the potato, are easily recognised microscopically on the addition of iodine. The fæces can also be incubated with water and the gas evolved measured. If actual starch grains are not seen, potato cells may be found occupied by iodophilic yeasts. Failure to absorb starch in full amount may be an individual peculiarity resulting in diarrhoea and flatulence, when it is easily dealt with by diminishing the amount of starch in the food, especially the vegetable forms such as potato. Otherwise starch signifies pancreatic deficiency and is concomitant with, though less frequent than, failure to digest fat.

A number of other chemical examinations of fæces have been proposed, such as determinations of diastase and of trypsin, but they have not, in my view, been sufficiently developed to be of diagnostic value.

Special Articles.

KING EDWARD'S FUND FOR LONDON.

ON Dec. 14th a meeting of the President and General Council of King Edward's Hospital Fund for London was held at St. James's Palace for the purpose of awarding grants to the hospitals and convalescent homes for the present year. The Lord Chancellor, Lord Hailsham, presided and read the following

Letter from the Prince of Wales.

Although I am back in England, I cannot just at present undertake any public engagements. I should be grateful, therefore, if you and Mr. Whitley and the Governor of the Bank of England would continue to act as President's Powers Committee until the end of the year, and I would ask you to tell the council how sorry I am not to be able to take the chair at the distribution meeting on Dec. 14th. I congratulate King Edward's Hospital Fund on the achievements of a year which has seen the completion of the Wells Legacies distribution, the issue of the Pay Beds report, the actual start of the contributory pensions scheme for nurses and hospital officers, the receipt of Sir Otto Beit's magnificent gift for the purchase of radium, and the attainment for the first time of an ordinary distribution of a quarter of a million. I approve the proposal to appoint a special committee to consider the position of the voluntary hospitals under the Local Government Bill, and I wish the King's Fund and the hospitals all possible prosperity in the coming year.

Lord Hailsham then moved from the chair:—

"The General Council of King Edward's Hospital Fund for London desire to express their profound sympathy with His Majesty the King, Patron and Past President of the Fund, in his illness, and their heartfelt wishes for a speedy and complete recovery. They desire also to convey with their humble obedient duty to Her Majesty the Queen, His Royal Highness the Prince of Wales, President of the Fund, and the other members of the Royal Family an expression of sympathy in their prolonged anxiety."

The resolution was seconded by the Rt. Hon. J. H. Whitley and carried unanimously.

The Position of the Fund.

Continuing, Lord Hailsham, after referring to the gift of £50,000 from Sir Otto Beit for the purchase of radium, said the annual distribution this year constituted in itself a great landmark in the history of the Fund, for it was the first time that the ordinary annual distribution had reached the total of a quarter of a million. In order merely to maintain the £250,000 the Fund had to receive during the year at least £90,000. This year's success had been largely due to some special donations: notably two of £10,000 each from two anonymous donors, one of whom had now helped them with gifts of varying amounts for six years running. This did not include Mr. J. J. Crosfield's gift of £10,000 to capital. The Fund had also received an exceptional amount in legacies during the year. Besides the £250,000 in ordinary grants to maintenance and building the list contained the first instalments of the special grants promised in aid of the contributory pension scheme for nurses and hospital officers. This scheme, which the Fund initiated, had now been adopted by 93 hospitals in London and by 58 hospitals in other parts of the country, making 151 in all with a total of nearly 21,000 beds, which was practically one-third of all the voluntary hospital beds in Great Britain and Northern Ireland. If these special grants were included, and also the final grants made last May out of the Wells legacies, the grand total distributed during this year would be no less than £290,000. The publication in July of the report of the Pay Beds Committee had been one of the principal items in the Fund's work. The transfer to the county councils of the infirmaries hitherto carried on under the poor-law would produce great changes in the hospital service, and it was hoped that great improvements would result. But it would be

necessary to work out a scheme by which the voluntary hospitals should continue to make their special contribution to that hospital service, which depended on the fact that both their management and their finance were voluntary. If the voluntary hospitals were not preserved, not only would huge additional sums have to come out of the rates, but the present spirit of the voluntary hospitals, which influenced all other hospitals in this country, would be lost and the whole system would become official. This was the last thing that was desired.

Hon. Treasurer's Statement.

Lord Revelstoke (hon. treasurer) said that last year the estimates enabled the Management Committee to recommend a distribution of £245,000. The League of Mercy contributed an additional £2000, thereby increasing the total to £247,000. In addition to the donation of £10,000 from Mr. J. J. Crosfield, receipts on capital account included a legacy of £3709 from Miss E. A. Marshall, and further sums of £2671 and £1500 from the estates of Sir Julius Wernher and Mr. Samuel Lewis, these two sums being additional to the very large amounts already received from these sources. Miss Marshall's legacy, in accordance with the provisions of her will, would be added to the "family fund" entitled the "Marshall Fund." This fund was established by her brother, Mr. H. W. Marshall, who inaugurated it by a gift of £10,000 3½ per cent. Conversion Stock last year, on the occasion of the luncheon at the Mansion House held to commemorate the thirtieth anniversary of the King's Fund. This was the first "family fund" to appear in the annual report, and it now amounted to £11,334, the whole of this sum being represented by permanent investments. It was interesting to note that, had it not been for the interest on the late Lord Iveagh's bequest of £60,000 received in 1927, the estimates in November, which computed legacies on the basis of the five years' average, would not have reached the £250,000, but would barely have exceeded last year's total of £247,000.

The League of Mercy.

Lord Marshall, in making the annual statement on behalf of the League of Mercy, announced that this year it was proposed to allocate £17,000 to the King's Fund. This was the same amount as the grant of last year, which was £2000 higher than that of the year before. Its grants this year to extra-metropolitan hospitals amounted to £8210. From the inauguration of the League in 1899 it had transferred to the King's Fund from its collections for hospitals a total of £132,034, and had made grants to hospitals outside London totalling £108,907, making a grand total of £540,941.

Grants to Hospitals and Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the Committee on the Distribution to Hospitals (including recovery and convalescent branches), which stated that the amount placed at the disposal of the Distribution Committee for allocation amongst hospitals and their recovery and convalescent branches at the present distribution was £248,000, as against £245,000 last year. The number of hospitals applying for grants was 141, the same number as in 1927—Ormond Maternity Home having dropped out of the list and an application having been received from Wembley Hospital, opened in June last. The Committee were pleased to see, from the King's Fund Statistical Report, that the steady progress of the hospitals was resumed in 1927 after a slight interruption in 1926, the first since 1922. Each of the main sources of revenue—voluntary gifts, receipts on account of services rendered, income from investments and legacies—showed an increase. The combined result, for all the participating hospitals taken together, was a small excess of income over expenditure, although there were still 56 hospitals with deficits for some of them serious. The increase in

Gift of Sir Otto Beit for Purchase of Radium.

The Chairman of the Management Committee (the Earl of Donoughmore) presented a report of the Committee on the gift of Sir Otto Beit for the purchase of radium, and moved recommendations to the effect that the best thanks of the General Council be tendered to Sir Otto Beit; that, until the General Council shall otherwise direct, the Management Committee shall have the powers of the General Council with respect to the utilisation of the gift of Sir Otto Beit so far as regards the purchase of radium, at such times and in such quantities as the Management Committee may judge expedient, and the arrangements as to the custody of any part of it while not on loan to a hospital; and that, until the General Council shall otherwise direct, the Distribution Committee shall have the powers of the General Council with respect to the administration of the gift of Sir Otto Beit, so far as regards the application of radium purchased with the gift by way of loan to hospitals.

The recommendations, having been seconded by Sir George Makins, were put and carried unanimously.

Scope of Operations of the King's Fund.

The Earl of Donoughmore then presented a report of the Committee on the scope of the operations of the King's Fund as follows, and moved that the action of the Committee be approved.

1. The Management Committee have had before them two applications for an extension of the Fund's scope of operations. 2. The maximum scope under the Act of Incorporation covers "Hospitals of London" defined as such "hospitals, convalescent homes, nursing homes, nursing institutions, lying-in institutions, dispensaries, medical missions, societies, or the provision of surgical or medical aid, or appliances, and institutions for the rest, relief, or cure of sick persons" as are situate within the outer limits of the Metropolitan Police District or treat persons resident within these limits. 3. The working sphere was last extended on Jan. 1st, 1925, and includes hospitals within 11 miles of St. Paul's and convalescent homes treating London patients. 4. Applications for extension have been received: (a) From hospitals between the 11-mile radius and the boundary of the Metropolitan Police District. There are about 17 of these, extending from Potters Bar to Purley, and from Hillingdon to Erith. (b) From the Central Council for District Nursing Associations in London which makes grants to 49 associations employing 300 nurses in London and the adjacent counties. (c) From the Cottage Benefit Nursing Association which states that it has 52 associations affiliated. 5. With regard to (a), the Management Committee, after consulting all the committees of the Fund, replied that, as the Fund had extended its radius as recently as 1925 so as to take in all the poorer districts up to the eastern boundary of the Metropolitan Police District, the Management Committee could not see their way at present to recommend the General Council to extend the radius in the other directions. 6. With regard to (b) and (c), the Management Committee replied to the effect that the demands on the resources of the Fund were so great that it had not yet been able to take in all the hospitals in the Metropolitan Police District; that if and when it felt able to extend its assistance to other institutions it would have to consider all the classes enumerated in the Act and to decide upon their relative claims; and that in these circumstances the Committee could not recommend an extension to include nursing associations at the present time.

The motion, having been seconded by Major-General Sir Cecil Lowther, was adopted.

Report of the Pay Beds Committee.

The Earl of Donoughmore then moved the recommendations of the Management Committee on the report of the Pay Beds Committee, which was circulated to members of the General Council and to the public in July, and was published for the considera-

tion of all concerned (see THE LANCET, July 28th, p. 175).

The Management Committee accordingly recommended that the General Council should: (1) express its concurrence in the general conclusions of the report of the Pay Beds Committee, as quoted in para. 4 above; (2) express its general approval of the conclusions of the Pay Beds Committee on the subject of an insurance scheme for the middle and professional classes, quoted in para. 5 above; (3) commend the whole of the report to the consideration of the hospitals, the medical profession, and the members of the classes concerned; (4) express its thanks to the members of the Pay Beds Committee, Sir John Rose Bradford, Sir Bernard Mallet, Mr. Warren Low, and Prof. Winifred Cullis.

The recommendations were seconded by the Right Hon. M. C. Norman (Governor of the Bank of England) and carried unanimously.

Position of the Voluntary Hospitals under the Local Government Bill.

The Earl of Donoughmore also presented a report of the Committee on the position of the voluntary hospitals under the Local Government Bill, and moved that—

"It will be necessary for the Council to delegate powers to the Special Committee,† and the Management Committee accordingly recommend that the Council should pass the following resolution—viz.: That, until the General Council shall otherwise direct, the Voluntary Hospitals (Local Government Bill) Committee shall have the powers of the General Council with respect to the following matters, that is to say: (a) to consider what steps should be taken to secure that during the consideration of the Local Government Bill by Parliament every endeavour should be made to maintain the existence of the voluntary hospitals as an essential part of the hospital system after the transfer of the poor-law infirmaries; (b) to consider what subsequent steps should be taken with the same object in relation to schemes which will come into operation after the passing of the Bill; (c) to make inquiries and collect information for the assistance of the Committee in the exercise of the foregoing powers; (d) to confer with other parties concerned; (e) to report from time to time to the General Council and, between the meetings of the General Council, to the Management Committee; and, with the concurrence of either body, to publish statements."

The motion was seconded by Sir Walter Lawrence.

Colonel Levita said that as Chairman of the London County Council, the head of the Public Health Services for London, he would like to express the pleasure of his colleagues at the appointment of this Committee.

Arrangements for 1929.

Lord Hailsham said that appointments for next year would be made by the Prince of Wales on Jan. 1st next. The following would be added to the Council: Lord Reading and Mr. Warren Low; Mr. Ernest Pooley, in place of Sir Leonard Lyle, who could no longer spare the time needed for Distribution Committee work; and Wing-Commander Louis Greiz, in place of Lord Marshall, who also for want of time could not continue on the Revenue Committee.

A vote of thanks to Lord Hailsham for presiding, proposed by the Lord Mayor, Sir Kynaston Studd, seconded by Prof. Winifred Cullis, and unanimously carried, terminated the proceedings.

† This Committee is constituted as follows: Right Hon. J. H. Whitley (chairman), Viscount Knutsford, Hon. Sir Arthur Stanley, Sir John Rose Bradford, P.R.C.S., Sir Berkeley Mordhan, P.R.C.S., Right Hon. Hugh P. Macmillan, K.C., Sir Herbert B. Cohen, Sir Edward Penton, Sir Cooper Perry, and Mr. V. Warren Low.

CENTENARY OF KING'S COLLEGE.—Mr. F. J. C. Hearnshaw, Professor of Mediæval History in the University of London, has written a "Centenary History of King's College, London," of which he is a Fellow. The book consists of 116 pages, and contains much information hitherto not available. It is to be published by Messrs. Harrap and Co., Ltd., 39, Parker-street, Kings-way, London, W.C. 2, early in the new year (price 21s.), and all royalties will go to the College Centenary Fund.

CHLOROFORM ADMINISTRATION:

SOME SAFEGUARDING DEVICES.

The following modifications of the Junker apparatus have been devised and put on the market to avoid the dangers inherent in the original model.

CHIRON CHLOROFORM INHALER.

(MAYER AND PHELPS, 59-61, CAVENDISH-STREET, LONDON, W.1.)

This inhaler has been designed to render it impossible to pump out liquid by wrongful attachment of bellows or by overfilling. The apparatus

FIG. 1.

FIG. 2.

consists (Fig. 1) of two bottles coupled together by their inlet tubes, leaving only the two outlet tubes available. In use, the bellows are attached to one of the outlet tubes (say to A1) of bottle A. Now, on pumping, the liquid in bottle A is driven through the inlet tube c into bottle B, with the result that bottle B is now working normally, that is, air will be driven through the inlet tube c, and vapour out of the outlet tube B1. Since both bottles are similar, exactly the same result is obtained if the bellows is attached to B1, that is, fluid will be blown from bottle B to bottle A, and vapour through the outlet tube A1. The tubes are placed in such a way that there is no danger of pumping out liquid if the

bottles are tilted, or even turned upside down. The danger of overfilling is entirely eliminated because the apparatus can only be charged in an inverted position (Fig. 2), and as the liquid in each bottle reaches the level of the top of the funnel no more can possibly be poured in, so that not more than a specified quantity can be in the apparatus at any time.

The price of the Chiron chloroform inhaler alone is £4 7s. 6d., or complete with bellows, tubing, and Tyrell's mask, mouth, and nasal tubes, £5 12s. 6d.

FIG. 4.

FIG. 3.

HEWITT'S MODIFIED JUNKER.

(KROHNE AND SESEMANN, 37, DUKE-STREET, LONDON, W.1.)

In this modification of Junker's apparatus by the late Sir Frederic Hewitt there is no possibility of the flexible tubes being interchanged, nor is there any likelihood of the bottle becoming tilted during the administration. As is seen in Fig. 3, air enters in the usual way through the hand-bellows, but the afferent india-rubber tube is much larger than that ordinarily used. The efferent tube which is contained within the afferent emerges from the latter at right angles immediately above the hand-bellows. The arrows in the figure show the direction of the currents. The air entering the bellows passes along the afferent tube system, bubbles through the chloroform, and then escapes by the efferent system. The stop-cock is turned off, the bottle may be placed horizontally, or packed away in a bag without any risk of chloroform escaping. The apparatus is used as shown in Fig. 4. The price, complete in case with nasal tube, is £5 5s.

Gift of Sir Otto Beit for Purchase of Radium.

The Chairman of the Management Committee (the Earl of Donoughmore) presented a report of the Committee on the gift of Sir Otto Beit for the purchase of radium, and moved recommendations to the effect that the best thanks of the General Council be tendered to Sir Otto Beit; that, until the General Council shall otherwise direct, the Management Committee shall have the powers of the General Council with respect to the utilisation of the gift of Sir Otto Beit so far as regards the purchase of radium, at such times and in such quantities as the Management Committee may judge expedient, and the arrangements as to the custody of any part of it while not on loan to a hospital; and that, until the General Council shall otherwise direct, the Distribution Committee shall have the powers of the General Council with respect to the administration of the gift of Sir Otto Beit, so far as regards the application of radium purchased with the gift by way of loan to hospitals.

The recommendations, having been seconded by Sir George Makins, were put and carried unanimously.

Scope of Operations of the King's Fund.

The Earl of Donoughmore then presented a report of the Committee on the scope of the operations of the King's Fund as follows, and moved that the action of the Committee be approved.

1. The Management Committee have had before them two applications for an extension of the Fund's scope of operations. 2. The maximum scope under the Act of Incorporation covers "Hospitals of London" defined as such "hospitals, convalescent homes, nursing homes, nursing institutions, lying-in institutions, dispensaries, medical missions, societies, or the provision of surgical or medical aid, or appliances, and institutions for the rest, relief, or cure of sick persons" as are situate within the outer limits of the Metropolitan Police District or treat persons resident within these limits. 3. The working sphere was last extended on Jan. 1st, 1925, and includes hospitals within 11 miles of St. Paul's and convalescent homes treating London patients. 4. Applications for extension have been received: (a) From hospitals between the 11-mile radius and the boundary of the Metropolitan Police District. There are about 17 of these, extending from Potters Bar to Purley, and from Hillingdon to Erith. (b) From the Central Council for District Nursing Associations in London which makes grants to 49 associations employing 300 nurses in London and the adjacent counties. (c) From the Cottage Benefit Nursing Association which states that it has 52 associations affiliated. 5. With regard to (a), the Management Committee, after consulting all the committees of the Fund, replied that, as the Fund had extended its radius as recently as 1925 so as to take in all the poorer districts up to the eastern boundary of the Metropolitan Police District, the Management Committee could not see their way at present to recommend the General Council to extend the radius in the other directions. 6. With regard to (b) and (c), the Management Committee replied to the effect that the demands on the resources of the Fund were so great that it had not yet been able to take in all the hospitals in the Metropolitan Police District; that if and when it felt able to extend its assistance to other institutions it would have to consider all the classes enumerated in the Act and to decide upon their relative claims; and that in these circumstances the Committee could not recommend an extension to include nursing associations at the present time.

The motion, having been seconded by Major-General Sir Cecil Lowther, was adopted.

Report of the Pay Beds Committee.

The Earl of Donoughmore then moved the recommendations of the Management Committee on the report of the Pay Beds Committee, which was circulated to members of the General Council and to the hospitals in July, and was published for the considera-

tion of all concerned (see THE LANCET, July 28th, p. 175).

The Management Committee accordingly recommend that the General Council should: (1) express its concurrence in the general conclusions of the report of the Pay Beds Committee, as quoted in para. 4 above; (2) express its general approval of the conclusions of the Pay Beds Committee on the subject of an insurance scheme for the middle and professional classes, quoted in para. 5 above; (3) commend the whole of the report to the consideration of the hospitals, the medical profession, and the members of the classes concerned; (4) express its thanks to the members of the Pay Beds Committee, Sir John Rose Bradford, Sir Bernard Mallet, Mr. Warren Low, and Prof. Winifred Cullis.

The recommendations were seconded by the Right Hon. M. C. Norman (Governor of the Bank of England) and carried unanimously.

Position of the Voluntary Hospitals under the Local Government Bill.

The Earl of Donoughmore also presented a report of the Committee on the position of the voluntary hospitals under the Local Government Bill, and moved that—

"It will be necessary for the Council to delegate powers to the Special Committee,† and the Management Committee accordingly recommend that the Council should pass the following resolution—viz.: That, until the General Council shall otherwise direct, the Voluntary Hospitals (Local Government Bill) Committee shall have the powers of the General Council with respect to the following matters, that is to say: (a) to consider what steps should be taken to secure that during the consideration of the Local Government Bill by Parliament every endeavour should be made to maintain the existence of the voluntary hospitals as an essential part of the hospital system after the transfer of the poor-law infirmaries; (b) to consider what subsequent steps should be taken with the same object in relation to schemes which will come into operation after the passing of the Bill; (c) to make inquiries and collect information for the assistance of the Committee in the exercise of the foregoing powers; (d) to confer with other parties concerned; (e) to report from time to time to the General Council and, between the meetings of the General Council, to the Management Committee; and, with the concurrence of either body, to publish statements."

The motion was seconded by Sir Walter Lawrence.

Colonel Levita said that as Chairman of the London County Council, the head of the Public Health Services for London, he would like to express the pleasure of his colleagues at the appointment of this Committee.

Arrangements for 1929.

Lord Hailsham said that appointments for next year would be made by the Prince of Wales on Jan. 1st next. The following would be added to the Council: Lord Reading and Mr. Warren Low; Mr. Ernest Pooley, in place of Sir Leonard Lyle, who could no longer spare the time needed for Distribution Committee work; and Wing-Commander Louis Greig, in place of Lord Marshall, who also for want of time could not continue on the Revenue Committee.

A vote of thanks to Lord Hailsham for presiding, proposed by the Lord Mayor, Sir Kynaston Studd, seconded by Prof. Winifred Cullis, and unanimously carried, terminated the proceedings.

† This Committee is constituted as follows: Right Hon. J. H. Whitley (chairman), Viscount Knutsford, Hon. Sir Arthur Stanley, Sir John Rose Bradford, P.R.C.P., Sir Berkeley Moynihan, P.R.C.S., Right Hon. Hugh P. Macmillan, K.C., and Herbert B. Cohen, Sir Edward Penton, Sir Cooper Perry, and Mr. V. Warren Low.

CENTENARY OF KING'S COLLEGE.—Mr. F. J. C. Hearnshaw, Professor of Medieval History in the University of London, has written a "Centenary History of King's College, London," of which he is a Fellow. The book consists of 416 pages, and contains much information hitherto not available. It is to be published by Messrs. Harrap and Co., Ltd., 39, Parker-street, Kingsway, London W.C.2, early in the new year (price 21s.), and all royalties will go to the College Centenary Fund.

CHLOROFORM ADMINISTRATION:

SOME SAFEGUARDING DEVICES.

THE following modifications of the Junker apparatus have been devised and put on the market to avoid the dangers inherent in the original model.

CHIRON CHLOROFORM INHALER.

(MAYER AND PHELPS, 59-61, CAVENDISH-STREET, LONDON, W.1.)

THIS inhaler has been designed to render it impossible to pump out liquid by wrongful attachment of bellows or by overfilling. The apparatus

FIG. 1.

FIG. 2.

FIG. 4.

consists (Fig. 1) of two bottles coupled together by their inlet tubes, leaving only the two outlet tubes available. In use, the bellows are attached to one of the outlet tubes (say to A1) of bottle A. Now, on pumping, the liquid in bottle A is driven through the inlet tube C into bottle B, with the result that bottle B is now working normally, that is, air will be driven through the inlet tube C, and vapour out of the outlet tube B1. Since both bottles are similar, exactly the same result is obtained if the bellows is blown from bottle B to A1, that is, fluid will be blown through the outlet tube A1. The tubes are placed in such a way that there is no danger of pumping out liquid if the

bottles are tilted, or even turned upside down. The danger of overfilling is entirely eliminated because the apparatus can only be charged in an inverted position (Fig. 2), and as the liquid in each bottle reaches the level of the top of the funnel no more can possibly be poured in, so that not more than a specified quantity can be in the apparatus at any time.

The price of the Chiron chloroform inhaler alone is £4 7s. 6d., or complete with bellows, tubing, and Tyrell's mask, mouth, and nasal tubes, £5 12s. 6d.

FIG. 3.

HEWITT'S MODIFIED JUNKER.

(KROHNE AND SESEMANN, 37, DUKE-STREET, LONDON, W.1.)

IN this modification of Junker's apparatus by the late Sir Frederic Hewitt there is no possibility of the flexible tubes being interchanged, nor is there any likelihood of the bottle becoming tilted during the administration. As is seen in Fig. 3, air enters in the usual way through the hand-bellows, but the afferent india-rubber tube is much larger than that ordinarily used. The efferent tube which is contained within the afferent emerges from the latter at right angles immediately above the hand-bellows. The arrows in the figure show the direction of the currents. The air entering the bellows passes along the afferent tube system, bubbles through the chloroform, and then escapes by the efferent system. The stop-cock controls both afferent and efferent tubes. When it is turned off, the bottle may be placed horizontally, or packed away in a bag without any risk of chloroform escaping. The apparatus is used as shown in Fig. 4. The price, complete in case with nasal tube, is £5 5s.

THE RIGBY MODIFICATION.

(DOWN BROS., LTD., 21-23, ST. THOMAS'S-STREET, LONDON, S.E. 1.)

THE device introduced by Dr. Morris Rigby, of Brighton, makes it impossible to expel the contents of the bottle through the inlet tube, which is provided with a ball-valve at the end inside the bottle (Fig. 5).

FIG. 5.

DOWN BROS. LONDON

The top of the valve is a sieve which breaks up the air stream into a spray, which is deflected downward by a hood, thus preventing the chloroform from splashing into the exit tube. The valve is simple, it cannot get out of order, and it does away completely with the danger from wrongly attaching the tubes. Messrs. Down Bros. do not stock or sell any form of Junker or Junker-Buxton inhaler which is not fitted with this ball-valve. The price of the chloroform inhaler, complete in case, is £3 8s. 3d., that of the chloroform bottle only, £1 5s. The extra cost of the valve fitted to customer's own chloroform bottle is 4s.

MAJOR ROUTH'S MODIFICATION.

(ALLEN AND HANBURY, LTD., 48, WIGMORE-STREET, LONDON, W. 1.)

THIS firm has for some time past discontinued the manufacture of Junker apparatus without a safety device. Major L. M. Routh's apparatus here illustrated (Fig. 6) is fitted with a cone-shaped valve to the inlet tube. Should an attempt be made to blow air the reverse way, the valve is blown on the seating so that the air cannot pass. This effectually prevents any liquid chloroform being blown out

FIG. 6.

should the bellows be attached to the wrong side. The price of the apparatus is 35s. complete.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Ætiology of Yellow Fever.

Prof. Max Kuczynski, of the Pathological Institute of Berlin University, recently read a paper before the Society for Internal Medicine on the ætiology of yellow fever. In his own experiments on the transmission of the disease to West African monkeys he had, he said, used the *Macacus cynomolgus* species whilst Stokes had employed *M. rhesus*. During these experiments both his assistant and himself had caught a disease showing all the symptoms of yellow fever. In monkeys as well as in the human species there was first a stage of bacteriæmia, followed by a functional collapse of the liver, which, like the spleen and kidneys, became swollen and fatty. Microscopical investigation showed a central necrosis of the hepatic lobules. It was now clear, said Kuczynski, that Noguchi's leptospira was not responsible for the disease. The true cause was a coccoid organism, growing in special nutrient media whose composition would be described later. This organism had a characteristic smell, which was noticeable in patients suffering from the disease, and it could be discovered in and cultivated from all the organs. By means of old and weakened cultures immunisation could be obtained. It was rather difficult to isolate because in monkeys vibrios were present which also grew rapidly in certain media. Prof. Jungmann said he had had Kuczynski and his assistant under observation in his hospital during their illness which clinically corresponded to yellow fever. There were two stages: in the first five days the symptoms were continuous fever, painful swelling of the liver, myasthenia, albuminuria, and a typical fœtor from the mouth, resembling that of foul meat. In the second stage the pulse and temperature were sinking, there was severe vomiting, redness of the skin, and extreme paralysis of the vessels. Jaundice was in both cases very slight, but there was leucopenia and an increase in the number of erythrocytes and in hæmoglobin. The treatment consisted of carbohydrates as food and injections of insulin and glucose. To spare the liver fatty food, albuminates, narcotics, and alcohol must, he said, be avoided.

Trouble in Hanover.

In Göttingen, Hanover, a child was brought by his mother to a medical man for an operation on the tonsils. As the boy could not be induced to open his mouth the doctor smacked his face so that he should begin to cry and thus involuntarily give a view of the throat. The procedure had to be repeated, and the result was that the face showed bruises and the right eye was swollen. Being prosecuted for causing bodily injury the doctor was found not guilty on the ground that the child's mother had agreed to an operation and this meant that he was authorised to take all measures which would facilitate it. The prosecution appealed to the High Court which annulled the judgment, however, because it did not regard smacking as a recognised technical method of inducing a patient to open his mouth, other means being available for the purpose. (In fact the child had opened his mouth for only a few seconds and then had closed it again.) The defendant was found guilty of assault but was fined only M.10 as he had not acted out of roughness but only by error of judgment. The *Verinsblatt*, the official organ of the Ärztevereins-Bund, agreeing with this decision, points out that there is no justification for the defendant's plea that smacks are allowed to facilitate certain operations. General acceptance of this view, it considers, would be detrimental to the good repute of the medical profession.

The Health of German Post-office Workers.

The Postmaster-General has issued regulations for the welfare of the numerous officials and employees of the Post-office. Old and unhealthy premises are to be rebuilt and also the official lodgings. The hours of service of the individual workers are to be regulated so as to allow enough leisure and playing grounds are to be put at their disposal. The regulations refer to the gymnastic exercises introduced some time ago with great success for telephone operators who cannot move for hours during their service. This system is to be introduced in other branches of the service where similar conditions of work exist. To tuberculous officials and employees not belonging to sick clubs a sum of M.500 (£25,000) is allotted to pay the costs of a stay in a sanatorium. After their discharge from the sanatorium they must be given posts where their work

is not too strenuous, and if necessary they must be transferred to a place with a better climate.

Maternity Homes and Hospitals.

The Prussian Statistical Office states that in 1926 there were in Prussia 135 maternity hospitals and similar institutions, having a total of 5101 beds. Of the 771,000 births registered, 12.4 per cent. took place in such places, as compared with 9.8 per cent. in the preceding year. This shows that an increasing proportion of women prefer to be confined in a hospital rather than in their home, a fact which from a hygienic point of view must be welcomed although it is disadvantageous to the individual practitioner. The number of cases of puerperal sepsis in these institutions was 23.4, with a mortality of 39.9 per cent.

During the same year in Prussia 939 accidents with electricity were reported, in about two-thirds of which the current was an alternating one. The number of fatalities was 112, and all but one of these were caused by an alternating current. In the exceptional case death was due not to the effect of the current itself on the body but to the severe injury which it produced by burning the clothes.

By an amendment to the Accidents Insurance Act, insurance will be extended to certain persons hitherto exempt—namely, members of fire brigades, certain classes of the staff of theatres, music-halls, and cinemas, nurses, laboratory assistants, and the medical staff of hospitals working in laboratories and radiographical institutes. Insurance against occupational diseases will henceforth include the seamy of seamen.

Dr. Koppen, the oldest member of the German medical profession, has died in Heiligenstadt, Thuringia, at the age of 94. Some months ago, on the seventieth anniversary of his qualification, he received congratulatory communications from President Hindenburg, the Minister of Home Affairs, the Medical Faculty of Halle University, where he had graduated, and the Medical Chamber of Thuringia.

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Sub-Lt. W. McO. MacGregor to be Surg. Lt.
Prob. Surg. Sub-Lieut. T. F. Tierney to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. G. Ormrod to be Lt.-Col., vice Lt.-Col. C. A. J. A. Balck Foote, to ref. pay.
Capt. G. Fleming, Reg. Army Res. of Off. R.A.M.C., relinquishes his appt. under Art. 507 (b), Royal Warrant for Pay and Promotion.
F. G. Brown and C. A. Levy to be Temp. Lts.

TERRITORIAL ARMY.

Maj. J. Paton, having attained the age limit, retires and retains his rank, with permission to wear the prescribed uniform.
T. J. C. MacDonald and R. M. Macfarlane to be Lts.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. W. Johnson, from the Active List, to be Maj.

ROYAL AIR FORCE.

Flight Lt. J. C. Osburne is promoted to the rank of Squadron Leader.
The following appointments are made: Flight Lts. E. C. K. H. Foreman to Princess Mary's R.A.F. Hospital, Islington; P. D. Barling to R.A.F. Base, Malta; L. Freeman to Bawtrey; J. O. Priestley to R.A.F. Depot, Uxbridge.

INDIAN MEDICAL SERVICE.

Lt.-Col. Sir L. Rogers (ret.) is granted the temp. rank of Maj.-Gen., whilst Med. Adviser to the Sec. of State for India and President of the India Office Med. Board.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

LOCAL GOVERNMENT BILL.

Transfer of Functions of Poor-law Authorities.

ON Thursday, Dec. 13th, the House of Commons went into Committee on the Local Government Bill, Mr. JAMES HOPE, Chairman of Committees, in the chair.

On Clause 1 Mr. A. GREENWOOD moved an amendment to transfer the functions of the poor-law authorities to the other kinds of local authorities besides the counties and county boroughs. He said that the Labour Party regarded with apprehension the transfer of poor-law functions to many of the county councils of England and Wales. Owing to many serious and real difficulties the county councils were the least representative of all the local governing bodies. In the exercise of poor-law functions it was important that real authority should rest with bodies on which people drawn from the classes that were most likely to need assistance could serve. The county councils were the worst possible bodies to act as poor-law authorities. His amendment did not propose that all borough or urban district councils should carry out all poor-law functions, but only those with a population of over 20,000. Certain kinds of institutional treatment could be more efficiently administered by a combination of authorities. For that the Minister made provision in the Bill. There was some question as to where they should draw the line. It was a question whether the limit should be a population of 20,000 or 50,000. His own view was that 50,000 put the line of demarcation rather too high and would rule out from the exercise of poor-law duties many local authorities that could well and effectively carry them out. Many of these smaller authorities represented the best in our local government life and it was a blow in the face and an implied insult that in this transfer of powers they should have been overlooked and placed in a position of subordination to the county councils.

Mr. HARNEY said that he had an amendment on the Paper making the population unit 50,000 instead of 20,000, and applying the transfer to rural areas as well as urban districts and non-county boroughs. He pointed out that many non-county boroughs and towns in rural areas were larger than many of the county boroughs.

Mr. PALIN, in supporting the amendment, said that he was afraid that the clause as it stood would not merely stereotype the existing poor-law but would make it worse than it was to-day.

Mr. CHAMBERLAIN, Minister of Health, said that the two amendments, which differed in degree rather than in kind, were both serious: in fact they were so serious that if either of them were carried it would to a large extent destroy one of the principles upon which this part of the Bill was founded. Both amendments tried to stereotype, at any rate to a considerable extent, the very difficulty which the Government were endeavouring to overcome. It was quite true that in Clause 29 a distinction was made between urban districts with populations of 20,000 and those with less, and in that respect the Government were following out the recommendations of the Royal Commission. But Mr. Greenwood had overlooked the fact that the financial responsibility under Clause 29 remained with the county council, which made all the difference. Mr. Greenwood's amendment did not propose to leave the financial responsibility with the county council and simply to transfer the work of administration to districts with populations of 20,000. The amendment gave these comparatively small authorities financial responsibility, and also, of course, liability. He was quite aware that the Maclean Committee recommended that urban districts or non-county boroughs with populations of 50,000 should be converted into county boroughs, but two things had happened since then. In the first place another Royal Commission sitting much later had recommended that the figure should be raised from 50,000 to 75,000. The second point was that they now had to consider the situation in the light of the de-rating proposals. The effect of those proposals was to narrow the field which was open to local authorities for the raising of rates, and therefore a charge or liability which formerly would have been spread over the whole of the existing field of rateable value must be concentrated on a reduced rateable value after the de-rating proposals had taken effect. That was a quite impossible point, and was alone sufficient to make it ment which would throw upon these bodies with their administration.

Miss SUSAN LAWRENCE, in supporting the amendment, said that in her opinion it was not the de-rating proposals that would make these areas so poor; it was the altogether artificial formula of distribution which the Committee had not yet discussed. The Minister's plan of redistribution would so sap the resources of some districts that they would not be able to carry on. The Committee were obliged to ignore all consideration of the proper functions of given areas, to sacrifice all considerations of obtaining homogeneous units of local government, in order to cut and chop the local authorities so as to fit in with the scheme devised in Part VI. of the Bill.

Mr. ERNEST BROWN said he could see no logical reason, apart from the artificial finance of the Chancellor of the Exchequer, for not accepting the proposal that 50,000 and more, whether county borough, non-county borough, urban district, or rural district, should be the financially effective unit for the administration of these functions.

Lieut.-Colonel FREMANTLE said he should like to put forward the public health side of the question. It was from that point of view that the Royal Commission on the Poor-law, amongst others, very strongly went for the county area as the unit of administration. The question of the poor-law included questions of health. It was not merely institutional treatment that was concerned, but they had to deal with health on broad lines. If the Committee adopted the proposals in either of the two amendments they would eliminate very largely from the main purposes of the Bill the essential factors in several of the conditions that must be treated over a large area.

Mr. E. BROWN asked how Colonel Fremantle could justify that statement in view of the fact that Rutland, a county with 18,000 population, was to get these powers, and Cambridge, a non-county borough with 59,000 population, would not?

Lieut.-Colonel FREMANTLE said that he admitted that there was great anomalies, but Clause 39 gave power constantly and immediately to a certain extent to rectify those anomalies. From every point of view on the health side, and from many other points of view, so long as they utilised local experience wherever possible, as was done in this Bill, it was necessary to have the larger coordinating factor under the county authority.

Mr. R. RICHARDSON, who said that he had been a county councillor for 25 years and a member of a board of guardians for 22 years, gave the opinion that things would be far worse under this Bill than they were at present. The duties of the county councils were already heavy enough without having fresh ones imposed upon them.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that anyone who had given consideration to the poor-law must come to the conclusion that the real hope of the heavily burdened areas was for the area of charge to be extended.

The amendment by Mr. GREENWOOD was negatived by 218 votes to 131.

Mr. HARNEY's amendment indicated by him in his speech was negatived by 223 votes to 133.

Mr. SIDNEY WEBB moved an amendment with the object of preventing county and county borough councils, to whom were being transferred these powers, from dealing with the able-bodied poor, that was the unemployed, under the poor-law.

Mr. CHAMBERLAIN said that Mr. Webb did not seem to make sufficient allowance for the fact that under the Bill they were transferring these duties from boards of guardians which had no powers to provide work to local authorities which had very large powers of that kind in their hands.

The amendment was negatived by 230 votes to 135, and Clause 1 was added to the Bill.

Powers to Combine Councils for Special Purposes.

On Clause 2 Miss SUSAN LAWRENCE moved to add the following proviso:—

"Provided that the Minister shall make orders for combining any two or more councils, whether councils of counties or county boroughs, covering suitable areas, for the purpose of dealing with vagrancy, and such orders shall include provisions for the suitable classification of all casuals, separating youths and mental deficient from other classes, and for ascertaining through the medium of the Employment Exchanges within the combined area the possibilities of employment."

She said that no people were so badly treated as the casuals. The food given to them was worse than any diet given in prison, except the punishment diet.

Sir D. NEWTON, while of opinion that Miss Lawrence's amendment went too far, urged the Minister of Health to see that vagrancy committees were set up which would operate over the country as a whole. It was most desirable that a uniform system of treatment should be enforced among local authorities.

Sir KINGSLEY WOOD said that the amendment would make it obligatory on the Ministry of Health to make orders combining authorities for dealing with vagrants.

There was no justification for such a peremptory provision. The provisions of the Bill were preferable and more in the interests of the casuals themselves.

The amendment was negatived by 202 votes to 131. The motion that Clause 2 stand part of the Bill was carried by 209 votes to 126.

Submission of Schemes.

On Clause 3, which provides that the county council and county borough councils shall within six months of the passing of the Act prepare and submit to the Minister of Health schemes for the administrative arrangements for discharging the functions transferred to the councils under this part of the Bill.

Mr. G. HALL moved an amendment to provide that the rural and urban district councils should be consulted by the county councils in regard to the preparation of schemes.

Mr. CHAMBERLAIN said that he thought that if the county councils could get their schemes prepared in time many of them would send copies to the district councils to obtain their opinion before submitting them to the Ministry of Health and they would be well advised to do so. His difficulty in accepting this amendment was that it interposed another process into the various measures which had to be taken in order to bring the scheme into operation on April 1st, 1930. He would, however, be willing to move an amendment to Clause 7 making it obligatory on the county council to send a copy of their scheme to each county district in their area when they submitted it to the Minister.

In reply to Captain MACMILLAN, Sir KINGSLEY WOOD said that the minor authorities would have adequate time given to them to make any representations to the Minister before an order was made.

The amendment was negatived and the clause was added to the Bill.

Provisions as to Alternative Powers of Giving Assistance.

On Clause 4 Sir RICHARD LUCE moved an amendment, the object of which was to remove the option given to local authorities in regard to the working of certain parts of the health services and to ensure as far as possible that in future those services which could be administered under existing Acts should be so administered and not by way of poor relief. He said that he had two further amendments on the Paper dealing with the same point. He realised that they would not completely carry out the transfer of the medical services from the assistance committees unless certain further action was taken under Clause 5, but if this amendment was accepted it would leave practically nothing to be done which would not be automatically done under Clause 5 where power was given to the county councils to direct that other parts of their duties should be transferred to committees other than the assistance committees. It did not seem that the Minister was carrying out the first of his proposals completely to co-ordinate the medical services in the area unless this were done. The very first of the Minister's proposals two years ago was to co-ordinate medical effort and to concentrate it. If a large portion of the duties was to be left to the new assistance committee, which was really only taking the place of the old guardians, except, of course, that it was under a different authority, the effect would be not to divorce the medical service from the other service, although that was so necessary for the effective co-ordination of the medical services. The assistance committee did not seem to him to be a really suitable committee to undertake the duties which would be imposed upon it in this way. It would always have as its first duty the provision of monetary assistance to the poor in the way that the old guardians gave it. There was no doubt that one of the great failures of the guardians in the past had been the administration of the medical service. There had been, of course, notable exceptions, but on the whole, speaking from a professional point of view, one could not say that the medical services for the poor provided by the guardians had been anything like as good as those administered through voluntary hospitals, and so on. Therefore it must be admitted that it would be advantageous to transfer such duties as were concerned with medical matters—such education came into it also—to those committees which were already devoting their time to and had been brought up to deal with these particular subjects in the best possible way. It was difficult to train a new committee in two distinct duties. The new assistance committee would have to be trained in the duty of medical relief. They would have to train these committees in work which other committees were already trained to perform and the work would be duplicated. Moreover, they would have a medical officer of health who was the adviser of the health committee and other committees that dealt with such matters. The medical officer would be compelled to divide his attention. Apart from that, it would be only fair to the sick poor to give them the full advantage in every way of the assistance

for the reduction in the amount of the subsidy and the reduction in their own contribution, were in a position to place orders for houses at £50 10s. less than before the cut was made. With regard to the output of houses, it had been suggested that the reduction in the subsidy had stopped building. The number of State-assisted houses completed in each quarter of 1926 before the alteration in the subsidy were: In the March quarter, 28,000; in the June quarter, 34,000; in the September quarter, 41,000; and in the December quarter, 40,000. In the March quarter of 1927 they went down to 38,000; in the June quarter they rose to 44,000; in the September quarter they rose to the tremendous figure of 90,000; and in the December quarter they dropped to 24,000. The present year had been characterised by a rapid increase in the output. In the first quarter it was comparatively small—20,000; in the June quarter it was 25,000; and in the September quarter it was up to 32,000. So that by September of this year they were within 5000 of the output of the quarter ended March, 1927. The total output in the three quarters of this year was 77,477, or nearly half as many again houses as for the whole of 1924. Taking into consideration the conditions all over the country, he had come to the conclusion that it was desirable in the present case to make the cut in the subsidy the same as it was before—that was the equivalent of £25 per house. He did not expect that as a result of this Order there would be a second fall in the price of houses to the same extent, but he was not satisfied that even now the price had reached the bottom level. But when he was told that the effect of this Order would be to raise the rent of houses he replied that those people who maintained that were wilfully shutting their eyes to the facts.

The motion approving the draft of the Order was carried by 241 votes to 146.

ROAD TRANSPORT (FIRST-AID EQUIPMENT) BILL.

In the House of Commons on Tuesday, Dec. 18th, Mr. RAMSDEN asked leave to bring in a Bill to regulate the first-aid equipment of public passenger service vehicles on roads. He said that the object of the Bill was to ensure that on all public passenger vehicles such as motor omnibuses and chas-a-banc there should be carried a first-aid outfit and that there should be someone on the vehicle competent to use it. The Bill would not apply to railway carriages, tramways, or trolley vehicles. The regulation as to the outfit and by when it should be carried would be left to the Minister of Transport.

[Leave was given to introduce the Bill, and it was read a first time. Dr. DRUMMOND SHIELDS was one of the backers of the Bill.]

GOVERNMENT AND DISTRESSED AREAS.

In the House of Commons on Thursday, Dec. 20th, the Supplementary Estimate for £295,625, including £155,000 as a grant-in-aid of the Lord Mayor's Fund for transference of unemployed workpeople and £20,000 for distressed mining areas in Scotland, was considered on report.

Mr. BALDWIN (Prime Minister) said neither the present nor any Government could do anything without the help of the community. The whole community more than ever was required to help in this matter of the distressed areas, and the most effective way in which the community could help was for employers to take in someone, if only one man, who came from those areas where he would never get employment and get him into a district where he could hope to get it. With the exception of the black spots the country as a whole was prosperous. It was perfectly obvious when they came to consider for a moment the grant-in-aid towards the Lord Mayor's Fund that now that the Government had made a contribution towards that fund it was quite impossible any more to draw any distinction between any classes of workers as far as relief was concerned inside a distressed mining area.

After considerable debate the report of the vote was agreed to.

CHRISTMAS ADJOURNMENT.

The House of Lords adjourned for the Christmas recess on Wednesday, Dec. 19th, until January 22nd. The House of Commons adjourned on Thursday, Dec. 20th, until January 22nd.

HOUSE OF LORDS.

WEDNESDAY, DEC. 12TH.

ROAD VEHICLES REGULATION BILL.

Viscount CECIL OF CHELWOOD moved the second reading of the Road Vehicles Regulation Bill, which requires all drivers to take out a licence after examination into their skill and physical fitness, and all motor vehicles to be provided with a mechanical check on their speed. He said that more than 5000 persons were killed every year through

accidents on the roads—the immense majority of them by motor vehicles. In addition 150,000 were injured every year and it was calculated that not less than 300,000 accidents to persons or property occurred on the roads every year. Four-fifths of these accidents took place during the daylight hours. That meant that about ten people were killed each day, or nearly one every hour of daylight; nearly one every two minutes was injured, and within a fraction of every minute there was an accident to person or property. In fact, the free use of the roads was denied to a great section of the King's subjects—the old, the infirm, and children. He believed that the present condition of things could be very great alleviated. From inquiries made by the Safety-First Council it appeared that with respect to 600 fatal road accidents 100 were due to excessive speed and between 300 and 350 were due to careless or confused crossings by pedestrians. He was satisfied that in the very large portion of the latter class of accident a contributory cause was that the motorist was going so fast that when the accident became obvious he was unable to pull up. He attached great importance to the provision for altering the level of roads as a check to fast driving. The Bill further provided that every licence must show that the motorist was insured against third-party risks.

Lord DENMAN moved the rejection of the Bill. He said that the object of the measure would command general acceptance. It was to the very drastic proposals by which the Bill sought to achieve that purpose that he objected. The Bill was regarded with disfavour by the motoring public. He agreed that the penalties for dangerous driving should be far more severe than they were to-day, and that some check should be placed on the issue of licences to people suffering from certain physical disabilities. The objection he saw to the proposal of a medical examination was the great expense that would be entailed. At first sight it might seem desirable to have a driving test, but he believed it to be the case that the independent committees which had inquired into the question had all reported against it.

After further debate,

The Marquess of LONDONDERRY (First Commissioner of Works) suggested that the Bill should be withdrawn. It had been torn to shreds and tatters in the course of the debate. He did not disagree with Lord Cecil on matters of principle, but with the methods of carrying out the suggestions that had been put forward. This was a matter to which the Government were fully alive and to which they were directing their attention.

Earl RUSSELL: You have been doing that for three years.

The Marquess of LONDONDERRY said that the Government were doing all that at the moment could be done to deal with this problem. Regulation of motor traffic was absolutely necessary, but it must be sympathetic rather than oppressive, and must not operate in any way that might hinder the development of what was a comparatively young and flourishing industry. The Government could not accept the Bill. In the first place, there was no time for it, and in the second a Royal Commission was sitting investigating the whole problem of the regulation of motor vehicles and the co-ordination of all forms of road transport. The provision relating to the rate of speed was retrograde in character and impracticable. Speed was by no means the greatest factor in motor street accidents. In 1926 20 per cent. of such accidents occurred at a speed of from one to five miles an hour and at a speed of over 20 miles an hour the percentage of accidents was only 4½.

After further debate,

The Marquess of SALISBURY (Lord Privy Seal) suggested that the Bill should be given a second reading on the condition that Lord Cecil should not press the matter any further, but that the Bill should be sent by the Government to the Royal Commission which could consider it and decide whether its provisions were workable or not.

Viscount CECIL said that if the noble marquess would amend his offer by saying that he would ascertain from the chairman of the Royal Commission whether he would present in a very brief period an interim report dealing with this question of the danger of the roads, he would be willing to accept it.

The Marquess of SALISBURY assented to the second reading of the Bill on the understanding that it should be referred to the Royal Commission with a view to an early report upon it, or to a Select Committee.

The motion for rejection was withdrawn, and the Bill was read a second time.

PRESERVATION OF INFANT LIFE.

TUESDAY, DEC. 18TH.

The Protection of Infant Life Bill was read the third time.

Following the third reading, Lord DARLING moved three amendments to Clause 1.

In accordance with the guillotine resolution, the question that Clause 4 stand part of the Bill was put from the Chair and agreed to without a division.

Duties of Public Assistance Committees.

On Monday, Dec. 17th, the House again went into Committee on the Local Government Bill, Captain BOURNE in the chair.

Clause 5 provides that an administrative scheme for the constitution of a public assistance committee shall be made by the county councils and county borough councils.

Mr. LANSBURY moved an amendment to delete the reference to the public assistance committee, and to provide that the scheme should provide for the delegation of the transferred functions to appropriate committees of the council.

Mr. CHAMBERLAIN, Minister of Health, in opposing the amendment, said that exactly the same ground had been covered by its supporters as on Clause 4. His answer to the amendment was exactly the same. It was not that there was any intention of encouraging local authorities to keep all the transferred functions for ever under the public assistance committees; his point was simply that it would be physically impossible to hand over at once to the appropriate committees all the varied functions which were to be transferred. A great many local authorities would be in the position of having no public hospital and only a poor-law institution. In order to make a proper scheme the new authority would have to survey all the various institutions. They could not make that survey and carry out the structural alterations necessary in a day.

Mr. SIDNEY WEBB said that the amendment which the Minister of Health would move later on would allow the London County Council to transfer to any of its committees any part of the functions which it was performing, whether they were performed under the Poor-law or under the Education or Public Health Acts. In other words, under the terms of this amendment the London County Council would be able to transfer to what was called the Public Health Committee not only the functions which it exercised under the Public Health Acts and other similar Acts, but also the functions which it exercised in regard to the sick and infirm and which could be carried out by the guardians and the education committees. All he asked was that the same freedom should be given to other larger authorities in the country, such, for example, as the town councils of Liverpool and Manchester.

The amendment was negatived.

Under the provisions of the guillotine motion, the discussion on Clauses 5 to 8 automatically came to an end at 7.30 o'clock, and Lieut.-Colonel Fremantle's amendment on the Paper providing that a public assistance committee should include persons experienced in the work of voluntary hospitals was therefore not debated. Another amendment, in the names of Sir RICHARD LUCE and Colonel FREMANTLE, providing that all matters relating to the exercise by the council of the transferred functions, except the raising of a rate or borrowing money, should stand referred to the public assistance committee, or to any other committee of the council as the council should so determine, was also passed over.

On Clause 6, which provides for the appointment of guardians' committees and subcommittees, another amendment by Colonel Fremantle was likewise cut out by the guillotine. This amendment was to the effect that the administrative scheme might provide for the appointment of joint committees of guardians' committees for county areas, either in one or more counties, and for the performance by them within the areas for which they acted of the powers conferred by the clause upon guardians' committees, or any of them.

On Clause 7, which provides that as soon as an administrative scheme has been submitted to the Minister of Health, the council submitting the scheme shall publish a notice in the local newspapers stating that the scheme has been so submitted, Dr. VERNON DAVIES had an amendment on the Paper providing that the councils should also furnish copies to the councils of the several districts wholly or partly within the county, together with copies of the notice. This amendment was also guillotined.

Disqualifications.

On Clause 9, which deals with disqualifications, Mr. SIDNEY WEBB moved an amendment providing that a person should not be disqualified from membership of the Council of a county or county borough by reason that he or a member of his family had been an inmate of any institution provided by virtue of the Lunacy or Mental Deficiency Acts. Mr. WEBB said that as the law now stood a man was a pauper if his wife or child had been taken to an asylum, and even if he had paid the cost of maintenance in that institution when it was charged to him by the guardians.

Mr. E. BROWN said that there was some doubt what relief given for maternity and child welfare in a maternity home constituted relief under the Bill.

Mr. CHAMBERLAIN said that a maternity home, or a similar institution, was covered by the words of the clause. So far as the Mental Deficiency Acts were concerned, the point raised by Mr. WEBB was quite clear. Under the Mental Deficiency Act of 1913, while the authorities were entitled to recover a sum towards the expenses of maintenance from the individual, they had no power to recover from the guardians. Therefore treatment in a mental deficiency institution was not poor relief. It was true that a pauper lunatic who was confined in an asylum and was chargeable to the guardians was disqualified under certain circumstances, but there, again, the consideration came in as to whether the person was receiving medical or surgical relief. When legislation was introduced to deal with the recommendations of the Royal Commission on the Lunacy Laws, no doubt the Lunacy Acts would be added to the list of Acts mentioned in Clause 4 of this Bill, and there would be a provision under the terms of this Bill.

Mr. WEBB said that it was not fair to disqualify 115,000 people in the meantime before the passage of lunacy legislation when the matter could easily be set right now.

Mr. CHAMBERLAIN replied that he was not sure that the matter could be so easily set right now, but he would give it further consideration.

The amendment was withdrawn. Clause 9 was added to the Bill. Clause 10 (Repeal of the Unemployed Workman Act, 1905), Clause 11 (Amendments to certain Acts), and Clause 12 (Alteration of the Constitution of Assessment Committees) were then passed under the guillotine, and the debate was adjourned.

Roads and Bridges.

In the House of Commons two further days were allotted to the Committee stage of this Bill. The report is unavoidably held over. Most of the sitting on Wednesday, Dec. 18th, was taken up in the discussion of the clauses dealing with the powers of the local authorities over roads, bridges, and so forth. On Clause 29, which provides that an urban district council for a district for a population above 20,000 may claim to exercise the functions of maintenance and repair of any county roads within its district, Colonel ASHLEY (Minister of Transport) stated that the Minister of Health had informed him that he had in contemplation a five years' census instead of a ten years' census. By the operation of the guillotine Clause 46 (Provisions as to Medical Officers of Health); Clause 47 (Qualifications of Certain Medical Officers and Health Visitors); Clause 48 (Maternity and Child Welfare Services); Clause 49 (Notification of Births); Clause 50 (Supervision of Midwives); and Clause 51 (Provision of Hospital Accommodation for Infectious Disease) were among the clauses which were added to the Bill without discussion. During the day Clauses 29 to 53 were added to the Bill and progress was reported, and the debate adjourned till after the Christmas recess.

THE HOUSING SUBSIDY.

On Wednesday, Dec. 12th, Mr. CHAMBERLAIN (Minister of Health) moved that the draft of the Order proposed to be made by the Minister of Health and the Scottish Board of Health with the approval of the Treasury under Section 5 of the Housing (Financial Provisions) Act, 1924, be approved. He said that in December, 1926, when the last cut in the subsidy was made, he stated that he had come to the conclusion that there was a definite relation between the amount of the subsidy and the cost of building. That was borne out by figures. In July, 1921, when the decision was made to shut down the Addison scheme, the price of non-parlour houses was on the average £665. By December, 1922, the price had come down to £346 per house. In April, 1923, a new Housing Bill was introduced with a subsidy which was equivalent to about £75 per house. A month afterwards the price rose from £346 to £368, and by January, 1924, it had gone up to £386. A further Housing Bill was then introduced and there was an increased subsidy equivalent to about £160 per house. In a month the price went up by £52 to £438, and later it reached £451, an increase of £65. There it remained until December, 1924. In the March quarter after the last cut was made the price decreased by £23 to £428. Since that time it had more or less steadily fallen until in the September quarter of this year it had reached £360, a decrease of £88 per house. They made a cut in the Exchequer contribution which was equivalent to £25 per house. If they added that sum to the corresponding reduction in the contribution of the local authority, which was half the Exchequer contribution, they had a total cut of £37 10s. If they deducted that from £88, which was the fall in price of non-parlour houses, they got a net reduction of £50 10s. in the price of a house. So that local authorities to-day, after making allowance

Correspondence.

"Audi alteram partem."

TONSILLECTOMY OR GALVANO-PUNCTURE ?

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 8th (p. 1209) Dr. W. S. Whitcombe pleads for the use of the electric cautery in cases of tonsillar infection. I claim some experience in this subject, firstly as a general practitioner, secondly as a clinical assistant in the throat department of a general hospital, and thirdly as a victim of the cautery who was eventually brought to health by the complete dissection of his tonsils. Arguing from the particular to the general, I will deal with my personal experience first.

After a period of exposure to mustard gas in late 1917, I developed a chronic tonsillitis with frequent exacerbations and, later, starting with a mild furunculosis, I lost all resistance to staphylococci, suffering from carbuncles and abscesses of increasing severity. As I had pus oozing from the crypta magna of each tonsil I saw a throat specialist at one of the stationary hospitals behind the line. I was at the moment in a field ambulance, and as I did not wish to leave my unit for an operation, these crypts were opened up with the cautery under cocaine. I rapidly became worse, and just after the Armistice developed a double quinsy. Meanwhile the skin infection increased, and I had at least 18 abscesses in the arm-pits. I had, of course, vaccine therapy, both stock and autogenous, as well as all the reputed lines of treatment, without avail. After I was demobilised I arranged to have my tonsils out, and the operation for dissection was carried out by Mr. Somerville Hastings. It was rendered more difficult by the adhesions caused in part by the cautery and also by the quinsies; but the improvement in my general health and my feeling of well-being within 14 days of that operation was, to me, little short of miraculous, and I have maintained a comparatively robust health, with no return of the staphylococcal infection, ever since.

It is difficult not to be prejudiced in favour of the operation for the complete removal of the tonsils after such an experience, but one tries to keep an even balance of opinion in dealing with cases of tonsillar disease at hospital and in private practice. But, by choosing the cases for operation and by setting a standard of signs and symptoms, it is undoubtedly possible to claim dramatic results in the improvement of health of both children and adults, such as were claimed in the recent article referred to in Dr. Whitcombe's letter. The symptoms and pathological changes due to focal infection in the tonsils are widespread and more often than not remote from the throat. I therefore set the following local tests for deciding whether tonsillectomy should be performed or not.

1. *Congestion*.—If there is an unvarying red area from the base of the tongue up the anterior pillar of the fauces and spreading over to the uvula, causing elongation thereof, the tonsils are suspect, even if there are no throat symptoms.

2. *Presence of pus*.—If on pressure from the lowest part of the tonsils upwards, pus or hard cheesy masses of revolting smell are exuded, tonsillectomy is advisable.

3. *Glandular enlargement*.—If there is increase in the size of the tonsillar cervical glands it would appear that the first line of defence has succumbed.

4. *Size of the tonsils*.—Mere enlargement of the tonsils without any of these signs is no justification for the operation unless it causes obstruction. It is remarkable in children how the tonsil varies in size from week to week without any sign of local or general disease. In adults it is often the small fibrous tonsil that causes systemic infection.

If a case is found where all the signs are positive and the general health undermined there is no question as to the dramatic improvement in health following the operation. Not perhaps so startling as the cure of a neuralgia after the removal of a septic stump or a carious infected tooth, but sufficiently so always to justify the complete removal. The dangers and

difficulties of dissection of the tonsils have been largely removed by the introduction of the Boyle Davis gag and, with proper anaesthesia, complete removal can be carried out with just as little or even less discomfort during the period of recovery as when the guillotine is used. The age of the patient does not appear to matter. I have had equally good results in a man of 68 and a child of 18 months. In both cases the recovery from the after-effects was rapid and the main symptom, intractable cough, was alleviated from the moment of operation.

It appears to me that the cautery must, in opening one or two large crypts, seal the ends of many smaller and result in a far more definitely enclosed infection; and it seems to be just as unscientific as the crowning of an infected tooth stump and as unjustifiable. Once a tooth is decayed and infected it is no longer any use, but a danger to the system. Nowadays one hears no plea for the retention of such stumps, although the teeth were placed in the body for a purpose. That purpose having failed their complete removal is logical, just as logical as is the complete removal of the tonsil and the appendix, once they succumb to infection and become no longer useful units in the human organism.—I am, Sir, yours faithfully,

C. BERKELEY WAY, M.B., B.S. Lond.

Finchley-road, N.W., Dec. 19th, 1928.

RADIUM AND CANCER.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to a paragraph headed Radium and Cancer in the *Times* weekly edition (Sept. 13th, p. 279), in which Mr. T. W. Paulin is quoted as having made an interesting statement as to the desirability of the London Hospital acquiring additional radium. In the course of this statement Mr. Paulin refers to a "new technique" for the application of radium which has given most encouraging results. He writes:

"The new technique which has been in use on the continent, at Brussels in particular, for some time past, consists in inserting a number of needles containing radium all round the cancerous growth—in favourable cases the growth is not only destroyed, but is prevented from spreading to the surrounding tissues."

This is perfectly correct save for the statement that the technique referred to is new, and the inference that it was evolved on the continent. The technique was fully worked out here in Dublin, and has been in constant use for the last 13 or 14 years. The nature and theory of the technique is dealt with by myself in a paper on the Local Application of Radium in Therapeutics, which appeared in the Scientific Proceedings of the Royal Dublin Society for May, 1914 (p. 290 et seq), and evidence of its remarkable practical success appears in a paper contributed by Dr. Walter C. Stevenson to the *Dublin Journal of Medical Science* for March, 1915.

The following quotation from the latter paper shows that Dr. Stevenson was then quite cognisant of the value of boundary treatment as referred to in Mr. Paulin's statement. Dr. Stevenson is speaking of a case of cancer which, originating in malignant polyp of the nose, had, among other lesions, caused proptosis of the eye. With the object of inhibiting the growth from increasing upwards and pressing on the eyeball, he arranged a line of needles immediately under the orbit. His treatment had the desired effect. Dr. Stevenson adds: "This systematic radiation of a growing edge is only possible by the needle method, and is one of its great advantages."

It is therefore evident that in every particular the technique Mr. Paulin refers to has been in use in this City since 1914 and 1915. So far as I know it originated and received its earliest trial and publication in connexion with the work done in the Radium Institute affiliated with the Royal Dublin Society.

I am, Sir, yours faithfully,

Trinity College, Dublin, Dec. 19th, 1928.

J. JOLLY.

The clause in its original form provided that any person who, with intent to destroy the life of a child capable of being born alive, by any wilful act caused a child to die before it had an existence independent of its mother, should be guilty of felony, to wit, child destruction, and should be liable on conviction thereof on indictment to penal servitude for life; provided that no person should be convicted of an offence under this section if it was proved that the act which caused the death of the child was done in good faith for the purpose only of preserving the life of the mother."

Lord DARLING said that on the Committee stage it was pointed out that there were occasions in which it was necessary at the confinement of a woman, in order to save her life, that the child about to come into the world should be destroyed. He fancied that it must be very rare that that should have to be done in good faith, but it was stated that such a case might arise, and that a third person might be indicted, through having acted in good faith. That was provided by the proviso in the clause beginning with the words "provided that no person shall be convicted" and so on, but it was then pointed out that it might be said that the onus was upon the person, who would be a third person, who had destroyed the child, to prove that he acted in good faith for the purpose of saving the life of the mother. He would therefore move three amendments which would result in the onus being put on the prosecution, so that it would be necessary for the prosecution from the start to prove—or else there would be no case to go to a jury—that the person who was accused of destroying the child had not done so honestly and in good faith. His amendments would make the proviso read:—

"Provided that no persons shall be guilty of an offence under this section unless it is proved that the act which caused the death of the child was not done in good faith for the purpose only of preserving the life of the mother."

Lord PARMOOR expressed satisfaction with the amendments, which he said made it quite clear that the onus of proof was on the prosecution.

The Lord CHANCELLOR said that Lord Darling had produced the amendments, partly after consulting him, to make it quite clear that the burden of proof had been shifted. He thought that the amendments did shift the onus of proof.

The amendments were agreed to and the Bill was passed and sent to the House of Commons.

HOUSE OF COMMONS.

TUESDAY, DEC. 18TH.

Medical Examination of Seamen.

Lieut.-Commander KENWORTHY asked the President of the Board of Trade whether he was aware that the room provided at Hull for the medical examination of seamen was unsuited for such purposes; and if he would take steps, in the interest of the health of seamen, to cause proper accommodation to be provided.—Sir PHILIP CUNLIFFE-LISTER replied: Medical examinations of seamen at Hull are not carried out at the Board of Trade offices, and no accommodation is provided there for the purpose. Any examination of seamen by the medical inspector appointed under the Merchant Shipping Acts would be held at his surgery, but no application has been received for such examination for some years.

Directors of Medical Services.

Sir HERBERT CAYZER asked the Parliamentary Secretary to the Admiralty for what period the Director of Medical Services held office; whether any extension in the period of the appointment was permissible; for what period the present director had held office; and whether any extension of his appointment was proposed to be made.—Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied: The appointment of Medical Director-General of the Navy is normally for three years, but this period may be extended if the Board of Admiralty thinks it desirable. The present Medical Director-General was appointed on July 1st, 1927, and the question of an extension, therefore, does not yet arise.

Sir HERBERT CAYZER asked the Secretary of State for War for what period the Director of Medical Services, Royal Army Medical Corps, held office; whether any extension in the period of the appointment was permissible; for what period the present director had held office; and whether any extension of his appointment was proposed to be made.—Sir L. WORTHINGTON-EVANS replied: The appointment of Director-General, Army Medical Services, is for four years, but an extension is permissible. As the present Director-General has held office for 2½ years only, no question of extension has arisen.

Sir HERBERT CAYZER asked the Secretary of State for Air for what period the present Director of Medical Services

had held office; whether at any time an extension of his appointment had been granted; whether it was proposed to grant him an extension in the future; and, if so, to what extent this would retard the promotion of junior officer serving in this department.—Sir S. HOARE replied: The tenure of the appointment of the Director of Medical Services dates from November, 1921. An extension has recently been granted until November, 1930. The question of any further extension will be considered on its merits when necessary in the light of the circumstances then existing. The fourth part of the question does not therefore arise.

Health of the Mercantile Marine.

Lieut.-Commander KENWORTHY asked the President of the Board of Trade whether he would state the personnel of the joint standing committee which has been set up to advise the Ministry of Health and the Board of Trade on matters affecting the health of the mercantile marine.—Sir P. CUNLIFFE-LISTER replied: The personnel of the Committee is as follows: Representing the Board of Trade: Sir Charles Hipwood, chairman; Mr. G. E. Baker, Mr. A. S. Hoskin, and Mr. C. J. Ovey, clerical secretary. Representing the Ministry of Health: Sir George S. Buchanan, Dr. H. A. Macewen, Mr. M. Heseltine, Mr. R. H. Crooke, and Mr. M. T. Morgan, medical secretary.

Pulmonary Tuberculosis.

Mr. ERNEST BROWN asked the Minister of Health the number of persons suffering from pulmonary tuberculosis awaiting admission to sanatoria on the latest available date.—Sir KINGSLEY WOOD replied: Separate figures for pulmonary cases are not available, but on Dec. 1st there was a total of 2541 persons who had been awaiting residential treatment for tuberculosis from local authorities in England and Wales for more than ten days. On the same date the total number of patients receiving such treatment was in excess of 21,000.

Deaths from Gas Poisoning.

Mr. BOWERMAN asked the Home Secretary whether a record was kept of the number of deaths by suicide and accident due to gas poisoning; and, if so, would he state the number of such deaths for the years 1913 and 1927 respectively.—Sir KINGSLEY WOOD replied: The deaths referred to are distinguished in the Registrar-General's mortality statistics, and the particulars asked for are contained in the following table, which shows the number of deaths in England and Wales registered during the years 1913 and 1927, which have been classified to gaseous poisoning, distinguishing accident and suicide.

Nature of gas as stated in death registers.	1913.		1927.	
	Accident.	Suicide.	Accident.	Suicide.
Coal gas	40	130	118	991
Carbon dioxide ..	8	2	1	—
Carbon monoxide ..	11	4	29	—
Other, or not stated, gases, fumes, &c. ..	30	24	14	4
Totals	89	160	195	995

The numbers of deaths shown above under "Accident" include a number of cases for which "Open verdicts" were returned at inquests.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee £703 was voted to 35 applicants. The following were some of the cases helped:—

Widow, aged 54, of L.L.D. and M.B. Owing to the lack of any special training is unable to earn more than £1 a week. Voted £36 in four instalments. Widow lives rent free in poor room.

Daughter, aged 68, of L.R.C.S. and L.S.A. Has supported herself for 21 years, but her employer has recently died and owing to her age she cannot now find work, and is practically destitute. Only income is old age pension of £26 a year. Voted £36 in four instalments. Other charities will be asked to assist. Applicant at present living with her nephew.

Daughter, aged 66, of M.D. On death of her parents was left eldest of four children and very badly provided for. Has supported herself by teaching until her health gradually gave way at 66. Her only income is £61 a year. Fund voted £35 in four instalments.

Widow, aged 71, of M.D. Has supported herself by keeping a private school, but owing to her age she has practically lost all her pupils and is almost destitute. Income £55. Voted £36 in four instalments. Other charities are now interested in this case and will give help.

Contributions should be sent to the Hon. Treasurer at 11, Chandos-street, London, W.1.

dial explanation, but the influence of the periphery especially the immediate periphery of the fovea the fovea is now firmly established. The point at the star is dealt with in detail in my book.

I am, Sir, yours faithfully,
London, Dec. 24th, 1928. F. W. EDRIDGE-GREEN.

NITROUS OXIDE.

To the Editor of THE LANCET.

SIR,—I should be grateful if you would correct an error which appeared in my article on the Pneumatic Operative Apparatus in your issue of Dec. 8th. As has been pointed out to me that nitrous oxide, which is stated to be used in an emergency, is as liable to explode with combustible bodies such as oxygen, and cannot therefore be looked upon as safe for use in the apparatus.

I am, Sir, yours faithfully,
Arley-street, W., Dec. 19th, 1928. W. H. OGILVIE.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 15TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 1 (last week 155); scarlet fever, 2504; diphtheria, 75; enteric fever, 38; pneumonia, 1248; puerperal fever, 49; puerperal pyrexia, 111; cerebro-spinal fever, 7; acute poliomyelitis, 3; acute poliomyelitis, 1; encephalitis lethargica, 25; continued fever, 1; dysentery, 5; ophthalmia neonatorum, 78. A case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the Metropolitan Asylums Board on Dec. 18th–19th was as follows:—Small-pox, under treatment 15; under observation, 1; scarlet fever, 2376; diphtheria, 2154; enteric fever, 14; measles, 47; whooping-cough, 427; puerperal fever, 21 (plus 9 babies); encephalitis lethargica, 73; poliomyelitis, 5; "other diseases," 20. At St. Margaret's Hospital there were 6 babies (plus 1 mother) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (2) from enteric fever, 22 (0) from measles, 9 (2) from scarlet fever, 47 (15) from whooping-cough, 42 (10) from diphtheria, 61 (16) from diarrhoea and enteritis under two years, and 61 (9) from influenza. The figures in parentheses are those for London itself.

The fatal cases of enteric fever outside London were reported from Sheffield 2, Sunderland 1. Newcastle-on-Tyne reported 5 fatal cases of measles, Liverpool 4, Stockton-on-Tees and Hull 3 each. Manchester reported 3 deaths from whooping-cough. Fatal cases of diarrhoea were reported from Stoke-on-Trent 5, Sheffield 4, Leicester, Nottingham, Liverpool, Manchester, and Leeds 3 each (Glasgow 5, Belfast 9). Manchester reported 5 deaths from influenza, Liverpool and St. Helens 3 each, no other provincial town more than 2.

The number of stillbirths registered during the week in the great towns was 263 (corresponding to a rate of 42 per thousand births), including 45 in London.

GIFTS FOR PURCHASE OF RADIUM.—Mr. William Cuttall has given £3000 for the purchase of radium for the treatment of cancer at Doncaster Infirmary. He has also given £1000 to the Yorkshire Cancer Research Fund and £500 to the Leeds Radium Fund.—King Edward's Hospital Fund for London has received an anonymous donation of £250 for the purchase of radium, to be used at the discretion of the Fund.

DAVYHULME HOSPITAL.—The new hospital built at Davyhulme, near Manchester, by the poor-law guardians of the Barton-on-Irwell Union has now been put in commission, and patients from the Patriarch Institution will be sent there. The hospital provides accommodation of 100 beds, and its total cost was £325,000, or £650 per bed, which is regarded as remarkably low.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation on Dec. 19th the degrees of M.B. and B.Chir. were conferred on M. T. Clegg, and the degree of B.Chir. on L. R. Janes.

At recent examinations the following candidates were successful:—

THIRD EXAMINATION FOR M.B. AND B.CHIR.

Part I., Surgery, Midwifery, and Gynaecology.—C. M. Barker, F. G. Booker, J. V. Broad, C. J. M. Dawkins, E. L. Edmondson, J. S. S. Fairley, W. R. Forrester Wood, J. C. Gordon, A. C. de B. Helme, C. Hill, J. H. Hopper, M. C. Hounsfield, T. A. A. Hunter, L. R. Janes, W. E. Joseph, P. G. S. Kennedy, R. W. Knowlton, O. L. Lander, J. F. V. Lart, G. E. Lewis, T. K. S. Lyle, F. H. McCay, A. D. Morton, E. J. Neill, W. G. Oakley, J. A. Pocock, W. Radcliffe, G. L. Robinson, J. W. Shackie, D. M. Stern, H. Taylor, V. Thorne Thorne, G. W. Willcox, A. W. Williams, L. K. Wills, G. N. Wood, B. Wright, A. B. Field and F. Ram, Newnham; B. M. Willmott, Girton; and K. Wilson, Newnham.

Part II., Physic, Pathology, and Pharmacology.—M. E. Albury, H. F. Bateman, C. F. Brockington, F. Bush, E. Clayton-Jones, A. J. Dix-Perkin, R. M. Dowdeswell, A. G. Eddison, W. A. Elliston, L. Foulds, C. A. Francis, J. L. Franklin, R. Gallimore, E. L. Graff, J. M. Graham, L. T. Hilliard, R. Hodgkinson, S. D. Isaacs, W. E. Joseph, J. Lloyd-Williamson, A. Maberly, H. Mallinson, J. K. Moore, J. B. Murray, J. D. R. Murray, J. L. Newman, E. A. E. Palmer, L. S. Penrose, G. W. Pimblett, J. H. Richmond, G. L. Robinson, J. I. Sapwell, S. W. Savage, C. W. Shaw, W. H. Simonds, E. T. O. Slater, C. L. Stote, H. S. Taylor Young, I. C. C. Tchaperoff, W. E. Underwood, J. H. Wainwright, F. H. Ward, G. W. Willcox, L. B. Winter; M. H. D. Carr, Newnham; and J. R. Lees, Girton.

UNIVERSITY OF SHEFFIELD.—At recent examinations the following candidates were successful:—

M.D.

Denton Guest.

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—Doris Butler, Dorothy Colver, and J. D. Gray.
Part I.—W. H. Carlisle, Frank Ellis, R. B. Gould, *Iris M. Moody, †T. H. Puller, Isaac Slesnick, Ethel H. Waddy, and J. H. Wilbourn.

* With distinction in forensic medicine.

† With distinction in forensic medicine and in public health.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College on Dec. 18th, with Mr. Alexander Miles, the President, in the chair, the following 31 successful candidates, out of 89 entered, who passed the requisite examinations between Sept. 27th and Oct. 8th, were admitted Fellows:—

B. Addington, L. T. Barclay, J. A. Bingham, J. G. Bogle, N. E. H. Box, A. W. Bowles, G. W. S. Brown, E. L. Button, D. Cameron, S. Dayal, D. Fettes, H. W. Fitzgerald, J. C. Forsyth, J. A. R. M. Hadley, Constance I. Ham, Muriel G. Henderson, D. Lamont, A. Macdonald, T. G. Millar, N. Fal, S. For, C. D. Read, B. W. B. Riley, C. P. Robinson, G. Saint, T. B. Seed, Sudhendu Sekhor Sen, E. L. Sergeant, H. K. L. Vaidya, F. K. White, and T. V. Woods.

FRENCH CONGRESS OF DERMATOLOGY.—The fourth Congrès des Dermatologistes et Syphiligraphes de Langue Française will be held at the Hôpital Saint-Louis, Paris, from July 25th–27th, 1929, under the presidency of Prof. Sabouraud. The subjects of discussion are the Polymorphous Erythemas, the Prurigos, and Malarotherapy in the Nervous Complications of Syphilis. The secretary-general is Dr. Clement Simon, 104 avenue Malakoff, Paris, XVI.

CRITICISM OF THE LOCAL GOVERNMENT BILL.—We have received the following statement from the National Baby Week Council, 117, Piccadilly, London, W.: "The National Baby Week Council views with alarm the proposals at present before Parliament to substitute 'block' for 'percentage' grants in support of the maternity and child welfare service. This service is a young and growing one that has not yet developed so as to secure to the children of the country as a whole the benefits made possible by the Maternity and Child Welfare Act. Hitherto 50 per cent. of the net approved expenditure on maternity and child welfare work has been borne by the State. Under the new Local Government Bill a block grant in respect of social and other services (maternity and child welfare, public health, roads, &c.) will be made to the appropriate local authority which will, except for minor safeguards in the Bill, itself decide how much of it is to be spent on maternity and child welfare. The question is—will maternity and child welfare receive an adequate proportion of the block grant to allow for much needed expansion, or will local factors operate to restrict expenditure on and hinder the progress of this vital work? The National Baby Week Council at its last meeting passed a resolution expressing its apprehension of the proposed change."

PURE NEPHROSIS.

To the Editor of THE LANCET.

SIR,—Everybody will agree with the terminal statement in Dr. Parkes Weber's letter that "in such matters mechanical explanations are not to be lightly accepted." Although Dr. Weber himself admits mechanical factors as playing at least a part in this disease—believing that the swelling of the epithelium of the convoluted tubules is sufficient to partially obstruct the outflow of water from the glomeruli—I fear that this statement may convince more than ever of the correctness of their attitude those who believe that most of the ills of the kidney and certainly pure nephrosis are due to some poison; and that it will thus prevent them giving such consideration to mechanical explanations as the subject deserves.

One has to remember that in spite of the wonderful chemical reactions which take place in the body, of the play of hormones and of internal secretions, man is a high-pressure machine; and that most if not all of the chemical changes only take place in virtue of man being a high-pressure machine. We have recently celebrated the Harvey tercentenary, we have seen the Harvey film, and Lenotre¹ has shown us the quagmire formed by the blood of victims round the scaffold during the Terror—how the blood pours out when the head is cut off. And it is not simply to make the blood go round and round that a high aortic pressure exists; it is to make the organs work that a high blood pressure is necessary. Especially do we know from Goll's experiments (1854) that a high blood pressure is necessary for renal activity; when the blood pressure is reduced the kidney fails to work, when the blood pressure is raised, the kidney works more efficiently. Certain physical conditions thus seem necessary for the maintenance of the normal. Is it to be believed that change of physical conditions cannot produce the abnormal? In every walk of life the environment (mainly of physical effect) shapes the individual; in every walk of life the internal pressure conditions determine health or disease.

Unfortunately, pathology—especially the pathology of renal disease—is all befogged because the complete mechanism (chemical and physical) of the normal is not yet known; the exact mechanism of the secretion of urine has not yet been certainly displayed. And since microbial invasion causes many diseases, since microbes obtained from the diseased part can now be seen—whilst physical forces are abstruse and cannot be seen (only their effects can be seen)—it is imagined that all visceral disease must be due to microbes or the toxins they produce or to kindred poisons, except indeed those in which some mechanical feature is so obvious that it cannot help obtruding itself on the consciousness of the observer. So grossly inclined to toxic processes is thought of to-day that it is safe to say that any pathological process due to a mechanical cause would not be ascribed to that cause unless the cause were manifestly evident. To-day, even in intestinal obstruction the toxæmia which arises is imputed to absorption of toxins from the gut; not to the reaction of the individual to the obstruction (a reaction mainly physical)—as though by injecting suitable antitoxins the toxæmia would be overcome and the patient presumably would feel well in spite of the persistence of the obstruction.

And, as regards the kidney, is it not amazing that so-called pure nephrosis should be attributed to such highly different poisons as microbial toxins on the one hand, and to non-microbial poisons, such as chloroform on the other. In 1909 Dr. Parkes Weber published a case of necrosis of the convoluted tubules found at autopsy in a man the subject of malignant disease of the prostate; anuria developed. The right kidney was incised, but the anæsthetic used is not stated.² The case simulated the suppression of urine

at times following labour—a condition imputed to a toxin specific of pregnancy. And in 1921 he published another interesting case—that of a woman who jaundiced; the gall-bladder was excised under anæsthesia; the patient died in three days and the post-mortem acute necrotic changes were found in the liver and in the convoluted tubules of kidneys—reminding one again of the condition of these organs in the "toxæmia of pregnancy." (In these were cases in which the renal changes in eclampsia were found in the non-pregnant—renal changes in the first case differed from usually found in eclampsia, it was only in the "more or less all" of the convoluted tubules of left kidney) having undergone a necrotic change.

It seems to me strange to impute the renal changes of eclampsia to a toxin specific of pregnancy (the same renal lesions in another case to a microbe toxin), the same renal lesions in a third case to chloroform (because the patient had had anæsthesia), and the same renal lesions in a fourth case to ether (because chloroform was not used). Especially is this so when it is manifest that in all these cases physical factors have been in play (and in these types have been displayed with certainty) and when, moreover, we know that emptying of the bladder rapidly in an elderly man with an enlarged prostate without an anæsthetic may produce a nephrosis at least an anuria. The man had an enlarged prostate, unable to pass water, developed high blood pressure and strains incessantly. A woman with the excised gall-bladder vomited persistently; the primigravida in hospital with an activity surpassing that of the still are maids. Are these factors sufficient to produce pathological changes in the kidneys—even to "nephrosis"? I am certain they are.

We are told not to accept mechanical explanations lightly. I agree, but this does not mean that mechanical explanations are to be considered lightly. The evidence indicates that mechanical explanations are worthy of the greatest consideration—that mechanical factors may not only play a part in the pathological process when it has begun, but may even be the very cause of its beginning. It is difficult to define, more subtle in their play than the effect of microbial or non-microbial poisons, the understanding of the physics of the kidney may not only illuminate the mechanism of the normal functioning of the kidney—the secretion of urine; it may even shed light on the rise of renal disease—the excretion of urine obviously abnormal, or even to our astonishment that puzzling condition, "no urine at all."

I am, Sir, yours faithfully,

R. H. PARAMORE, F.R.C.

Rugby, Dec. 22nd, 1928.

THE RODS AND CONES.

To the Editor of THE LANCET.

SIR,—Mr. Wohlgenuth does not seem to me to have read my letter very carefully. Emphatic approval of my letter was given; as a matter of fact, my letter was a considerable discussion but every statement was supported by my theory. Prof. A. v. Tschernak, one of the leading authorities on vision, has stated that there was not a single fact or observation in my paper that he could not support from his own observations and he subsequently addressed a letter supporting my views. It is curious that Mr. Wohlgenuth should have selected an extract from my book of 1891 when he could have selected matter so much better dealt with in my book "Physiology of Vision."³ The explanation is admitted in the book he mentions.

¹ Parkes Weber: Case of Intrahepatic Cholestasis with Acute Necrotic Changes in the Liver and Renal Tubules following Ether Anæsthesia. *Clinical Medicine*, 1909, 1, 11. March 16th, 1921.

Notes, Comments, and Abstracts.

THE CONCEPT OF PREDISPOSITION

BY JULIUS BÁRON, M.D. BUDAPEST.

THE last decade may justly be called the period ofnaissance of the theory of constitution and predisposition. A great deal has been done in a short time to substantiate the theory, but the practical results of these efforts are at present of little significance to the practitioner, because the new ideas are not clearly defined and so their application is led to faulty or contradictory results. On the other hand, he would be gained by their exact definition, for concepts can only be accurately defined when their content has been clearly set out. The definition is just the summary of the analyses of the concept in question, and a very large number of analyses are still necessary in order accurately to define constitution and predisposition. The present paper is a contribution to this work.

The Accepted View.

As a starting-point let us choose a statement to criticise. This statement has not been made elsewhere, at any rate in its present form, but it can be regarded as the generally accepted view of predisposition. "Two healthy individuals are exposed to the same external conditions and one falls ill, while the other does not. We say that the sick person has a greater predisposition to the malady than the healthy one." On analysing this statement, our attention is arrested by the expression "to the same external conditions." It is obvious that no two individuals can be exposed to the same conditions in a mathematical sense. Let us, however, regard it as possible, and then disregard the conditions which we do not consider important for the development of the illness. Which these are we must decide on the basis of experience. The train of thought is somewhat as follows: We know from experience that, as a rule, no more persons die of typhoid on a Tuesday than on a Friday—so that the day of the week is of no importance in the onset of the disease. Therefore experience can influence our results in comparing the predisposition of two individuals to the same malady. An alteration in our experience can, in the same way, bring about a change in the result of the comparison. The expressions "remaining well" and "falling ill" must also be examined more closely. It is a constantly reiterated fact that there is no strict line of demarcation between "being ill" and "being well." Such a line can only be arbitrary. The following possibilities remain. The boundary between illness and health can, for a given disease, be drawn arbitrarily in two places; if it is drawn the first A remains well while B falls ill, and if it is drawn the second B remains well and A falls ill. The arbitrary boundary between health and sickness is, therefore, the deciding factor in comparing the predisposition of the two individuals.

We must consider also another possibility. A and B are exposed to the same external conditions, which we will call K. A is taken ill and B remains well, so that the predisposition to the disease is greater in A than in B. Let us assume that A and B are exposed to the conditions K and B falls ill while A remains well. If the view of predisposition is to retain the meaning described in our statement, we must assume that such contradictory conditions as K₁ and K₂ are not possible. The possibility of such conditions is, however, quite an open question, and we even regard it as very probable.

A Mechanical Analogy.

Finally, let us discuss whether we are justified, when investigating the cause of an illness, in separating the external conditions from the predisposition, "internal conditions," and setting them in opposition to one another. We can throw some light on this question by an analogy. Instead of a healthy individual, let us examine a well-defined mechanical system. As analogies for illness and health let us admit two well-defined possibilities of alteration in the system under certain external conditions. As both external and internal conditions can be easily reviewed the conception of predisposition can be studied especially well in this case. Let us imagine a homogeneous, accurately proportioned and solid die, with three sides painted white and three black. We place the die accurately on a certain point of a strong spring and, having compressed the latter to a given degree, release it in a prearranged manner so that the die falls on a relatively large, rigid, and perfectly horizontal surface. There are two possibilities; the uppermost surface of the die is either white or black. If we repeat the experiment frequently under the same conditions we can easily convince ourselves that the possibilities of the two cases are equal.

We cannot foretell the result of any one experiment, even with our knowledge of the various internal and external conditions. If we take two absolutely similar dice, and assume that in an experiment the one shows black and the other white, we must assume, according to our hypothesis, a greater predisposition for black in the first die and a corresponding predisposition for white in the second. It is clear that, in this case, the conception of predisposition has been wrongly applied. If we reflect how it is possible for the experiment to lead to various results, under the same external and internal conditions, then we see that the mistake lies in the abstract conception of "the same conditions." In this case we cannot know whether some apparently quite insignificant factor did not have a decisive influence on the result. Mathematically speaking, identical conditions cannot be produced, and the result varies according to numerous extremely insignificant variations which we neglect in reproducing "the same conditions" and which, even when they can be easily studied, can never be calculated. They are summarised in the concept of "chance." Let us now imagine that inside the die, near one of the white surfaces and opposite a black surface, is a small body of great density. This transfers the centre of gravity from the geometrical centre towards the white surface. In this case a "black" results more frequently than a "white," and one can logically assert that the die is more predisposed to "black" than to "white" and has a greater predisposition to "black" than the first die. Yet it is very possible that if one experiment only is made with both dice the die with "black" predisposition might turn up white, and vice versa.

We have confined ourselves so far to a system of which the internal conditions have remained unchanged throughout the experiments. The patient who has convalesced, on the other hand, often shows an altered predisposition to the disease. In order, therefore, to complete our analogy, let us imagine that part of the interior of the die is semi-liquid and that the small body is suspended in this part, but is not moved by gravity alone. Now, the centre of gravity alters its position during the course of a single experiment. If we look at the die from the outside only we cannot determine its predisposition, even by experiment. If we assume that the position of the heavy body only alters markedly after the completion of the experiment, then we can express an opinion on the predisposition of the die, but only after an autopsy (i.e., opening the die or X raying it) can we be sure of our statements. Given a number of such dice, in which the small heavy body can take up any position, and excluding autopsy, one could only speak of a predisposition if certain external easily determinable qualities were present in combination with definite types of predisposition. The occurrence of such combinations could be determined along statistical lines.

Conclusions.

One can only speak of a greater or lesser predisposition to a given illness when definite, easily determinable qualities occur in conjunction with a greater or lesser frequency of the illness, the qualities being determinable either through the experience that they are necessary or merely by statistical methods.

Given the same external conditions, the assumption of a greater predisposition on the part of the sick person only leads to a confusion of the idea of predisposition.

PERIODICITY IN DISEASE PREVALENCE.

At a meeting of the Royal Statistical Society held on Dec. 18th Mr. H. E. Soper, of the National Institute for Medical Research, discussed the interpretation of periodicity in disease prevalence. The fact that epidemic diseases often come upon us in the manner of surges, attended with great inconvenience and fraught with many special dangers when at their height, should be sufficient incentive, he thought, for a close study of the fluctuations in disease prevalence, and many attempts to account for the periodic nature of the visitations of sickness have from time to time been made. Amongst the various theories put forward to account for epidemic recurrence, perhaps the most favoured theory presents a picture of a rise and fall in the new cases of a contagious disease as consequent upon a glut and dearth of susceptible persons; for, clearly, if there is a limit to the numbers who can contract the disease, the action may be supposed to go after the manner of a pendulum, where, as the energy of flow becomes exhausted, the energy of potential activity gets stored up, to be released again when motion recommences. The stored energy is the accumulation of susceptible children, by birth. By means of arithmetic and algebra a simple supposition in regard to the delayed or lapsing infectivity of an infected person, combined with a supposition of a constant inflow by birth of susceptible children, can be shown to lead to an ever-sustained periodic wave, or swing of the epidemic pendulum, whose period could be interpreted. These idealised waves do not, however, give a very true replica of the curve of

WE regret to announce the death of Dr. Dawson Fyers Duckworth Turner, F.R.S. Edin., hon. consulting physician in radiology to the Royal Infirmary, Edinburgh. He died at Godalming on Dec. 25th, as the result of X ray dermatitis, in his seventy-second year.

INTERNATIONAL POST-GRADUATE COURSES IN BERLIN.—A number of medical courses have been arranged for post-graduates, and there will be a special series in March and April, the subjects including cardiology, urology, surgery of breast and stomach, and radiology. The information bureau of the Kaiserin Friedrich-Haus, Luisenplatz 2-4, Berlin, N.W. 6, will send further particulars on request, and is able to arrange attendance at clinics and assist in procuring lodgings for those who need them.

HEREFORDSHIRE GENERAL HOSPITAL.—This institution is to be enlarged from 110 to 140 beds at a cost of £80,000. The money in hand for the purpose is about £23,000, but the Court of Chancery has yet to decide whether there is power to sell sufficient securities to make up the balance.

DONATIONS AND BEQUESTS.—Mr. Walter George Nicol, of 5, Lansdowne-place, Brunswick-square, London, W.C., who left estate of the value of £112,991, left over £13,000 in various bequests, and the residue of the property equally between the London Hospital and King Edward's Hospital Fund for London, expressing the desire that the governing body of the London Hospital (if it should think fit) should associate the name of Nicol with some work or object upon or for which the said share of the residue or some part thereof may be expended.—Mr. James Porter, of West Park House, Leslie, Fife, left £1000 to the Edinburgh Royal Infirmary and £500 to the Kirkcaldy Cottage Hospital.—The Manchester Royal Infirmary has received a legacy of £1200 from the late Mr. George Whitaker, and an anonymous gift of £200.—Alderman J. Foster Clark, of Maidstone, and Mrs. Foster Clark have promised a joint contribution of £30,000 towards a proposed extension of the West Kent General Hospital at Maidstone.—Sir Charles Sissmore Tomes, F.R.S., of Mannington Hall, Norfolk, and Wigmore-street, W., left £208,899. Subject to certain provisions he left his property upon trust for his daughter. In the event of his daughter leaving no issue he gave £2000 to the Royal College of Surgeons of England for the foundation of a Research Fellowship in Odontology, "in the widest sense of the word," or in the augmentation of the Sir John Tomes Prize, as the Council of that body may see fit; and £1000 each to the Norfolk and Norwich Hospital, the Middlesex Hospital, the Royal Dental Hospital, the Royal Medical Benevolent Fund, and the British Dental Association Benevolent Fund.—Mrs. Emily Harris Hollingsworth, Sutton Coldfield, left £1250 to the General Hospital, Birmingham, to endow a bed in memory of her husband.—The King has sent contributions amounting to £3510 to local charities from the Windsor Castle State Apartments Fund. Of this the King Edward VII. Hospital receives £1202.

Medical Diary.
